trial code for gsm a7670c

8 hours ago

To test your **GSM A7670C** 4G module, you can use a simple Arduino "Serial Passthrough" sketch. This code allows you to send **AT commands** directly from your computer to the module via the Arduino, which is the best way to verify if the module is working and registered on the network. Arduino Forum +2

1. Arduino Serial Passthrough Code

This code bridges the communication between your PC's Serial Monitor and the A7670C module. Arduino Forum +1

cpp

```cpp
#include <SoftwareSerial.h>

// Connect A7670C TX to Arduino Pin 2, RX to Arduino Pin 3
SoftwareSerial A7670Serial(2, 3);

void setup() {
  // Serial Monitor Baud Rate
  Serial.begin(115200);

  // A7670C default Baud Rate (usually 9600 or 115200)
  A7670Serial.begin(9600);

  Serial.println("A7670C Ready. Type AT commands in Serial Monitor.");
}

void loop() {
  // Read from A7670C and send to Serial Monitor
  if (A7670Serial.available()) {
    Serial.write(A7670Serial.read());
  }

  // Read from Serial Monitor and send to A7670C
  if (Serial.available()) {
    A7670Serial.write(Serial.read());
  }
}
```

Use code with caution.

2. Critical Testing Commands

Once the code is uploaded, open your **Serial Monitor** (set to 115200 baud and "Both NL & CR") and type these commands: Arduino Forum +4

- `AT` — Should return `OK` (Confirms basic communication).
- `AT+CPIN?` — Should return `+CPIN: READY` (Confirms SIM card is detected).
- `AT+CSQ` — Checks signal strength (e.g., `+CSQ: 20,99`). Higher is better.
- `AT+CREG?` — Should return `+CREG: 0,1` or `0,5` (Confirms network registration).
- `ATI` — Displays module manufacturer and model details. Arduino Forum +4

3. Wiring Diagram (Arduino Uno)

A7670C Pin	Arduino Pin	Notes
TX	D2	Module Transmit to Arduino Receive
RX	D3	Module Receive to Arduino Transmit (Use 1.8V/3.3V divider if needed)
GND	GND	Common ground must be connected
VCC	External 5V/2A	**Crucial:** Do not power from the Arduino 5V pin; use an external supply.

4. Advanced: Sending an SMS

If your manual AT command tests pass, you can use this snippet to send a test message: Arduino Forum +2

cpp

```cpp
void sendSMS() {
  A7670Serial.println("AT+CMGF=1"); // Set SMS to text mode
  delay(500);
  A7670Serial.println("AT+CMGS=\"+91XXXXXXXXXX\""); // Replace with target
  delay(500);
  A7670Serial.print("Hello from A7670C!");
  delay(100);
  A7670Serial.write(26); // Sends CTRL+Z to finish the message
}
```

Use code with caution.

Would you like the **full code for an ESP32** setup or instructions on how to **upload data to a cloud platform** like ThingSpeak?

I am using it with esp32 so give the connections and code both to test it with a m2m sim

8 hours ago

To test your GSM A7670C with an **ESP32** using an **M2M SIM**, you need a stable power source and a direct serial bridge to configure the specific APN required by M2M providers.

1. Wiring Connections

The ESP32 uses **HardwareSerial2** for reliable communication at 115200 baud.

TXD	TXD
GPIO 16 (RX2)	Data from module to ESP32

Arduino Co Developme
I think the mo baud rate (ch

GND **GND**	GND **Common Ground** is mandatory
VCC **External 5V/2A**	VCC **Do NOT use ESP32 5V/USB**. Use an external adapter or buck converter.
PWRKEY **GPIO 4**	PWRKEY (Optional) Used to programmatically power the module on.
ESP32 Pin	**Description**

2. ESP32 Test Code (Serial Bridge)

This code acts as a bridge between your PC and the A7670C. It is essential for M2M SIMs because they often require manual APN configuration. Arduino Forum +1

cpp

```cpp
#include <HardwareSerial.h>

// Use ESP32 Hardware Serial 2
HardwareSerial simSerial(2);

#define RXD2 16
#define TXD2 17
#define PWR_KEY 4

void setup() {
  Serial.begin(115200); // PC Serial Monitor

  // A7670C defaults to 115200 baud
  simSerial.begin(115200, SERIAL_8N1, RXD2, TXD2);

  // Optional: Pulse PWRKEY to turn on the module
  pinMode(PWR_KEY, OUTPUT);
  digitalWrite(PWR_KEY, LOW);
  delay(1000);
  digitalWrite(PWR_KEY, HIGH);

  Serial.println("ESP32 & A7670C Bridge Ready. Enter AT commands below:");
}

void loop() {
  // Bridge A7670C response to Serial Monitor
  while (simSerial.available()) {
    Serial.write(simSerial.read());
  }

  // Bridge Serial Monitor input to A7670C
  while (Serial.available()) {
    simSerial.write(Serial.read());
  }
```

```
}
```

Use code with caution.

3. M2M SIM Configuration Commands

M2M SIMs usually have a **private APN**. Use these commands in the Serial Monitor (set to **Both NL & CR**) to verify and connect:

- **Check SIM Status:** `AT+CPIN?` — Should return `+CPIN: READY`.
- **Check Signal:** `AT+CSQ` — Should return a value (e.g., `20,99`). Anything above 15 is good.
- **Set M2M APN:** `AT+CGDCONT=1,"IP","your_m2m_apn"` — Replace `your_m2m_apn` with the APN provided by your vendor.
- **Activate Context:** `AT+CGACT=1,1` — Manually activates the data connection.
- **Check IP Address:** `AT+CGPADDR=1` — If successful, it returns the IP assigned to your M2M SIM. Arduino Forum +4

4. Key Troubleshooting

- **Baud Rate:** If you see "junk" characters, the module might be at a different baud rate. Try changing `simSerial.begin(115200...)` to `9600`.
- **Power Spikes:** If the module resets (Netlight stops blinking) when connecting, your power supply isn't providing enough current. Add a **470uF capacitor** across the module's VCC and GND. Arduino Forum +1

Do you need a code snippet to perform a **specific M2M task**, like sending sensor data via **MQTT** or **HTTP POST**?

it continously shows garbage values

8 hours ago

If your **A7670C** is outputting garbage values to the **ESP32**, it is **almost always due to a baud rate mismatch, voltage level issues, or inadequate power**. ESP32 Forum +1

1. Fix Baud Rate Mismatch

The A7670C typically defaults to **115200 bps**, but some breakout boards are fixed at **9600 bps**.

- **Step 1:** Change your code to `Serial2.begin(9600, SERIAL_8N1, 16, 17);` and test.
- **Step 2:** If that fails, revert to `115200` but ensure your **Serial Monitor** (the bottom-right dropdown in Arduino IDE) also matches exactly.
- **Step 3:** To force a fixed speed once you get a response, send the command `AT+IPR=115200` followed by `AT&W` to save it. OceanLabz +1

2. Check Logic Voltage (1.8V vs 3.3V)

The raw A7670C chip uses **1.8V logic**, while the ESP32 uses **3.3V**. Arduino Forum +1

- **If you have a breakout board:** Most have built-in level shifters, but if yours doesn't, the ESP32 might not "see" the 1.8V signals correctly, causing corruption.

Arduino

- **Fix:** Use a **Logic Level Converter** to shift the signals between 1.8V and 3.3V. Arduino Forum +1

3. Verify Common Ground

Garbage values often occur when the two devices don't have a shared reference point.

- **Action:** Ensure a physical wire connects a **GND pin** on the A7670C directly to a **GND pin** on the ESP32. Arduino Forum +1

4. Solve Power Spikes

This module draws up to **2A** during network bursts. If the voltage dips even slightly during transmission, the serial buffer will corrupt and show junk. ESP32 Forum +2

- **Fix:** Use an external **5V/2A or 12V adapter** (depending on your board) rather than powering via the ESP32 or a USB port. Arduino Forum +1

Quick Testing Table

Troubleshooting Step	Action to Take
Baud Rate	Try `9600` then `115200` in both code and Serial Monitor.
Wiring	Swap RX (GPIO16) and TX (GPIO17) to ensure they aren't reversed.
Ground	Confirm **Common Ground** between ESP32 and Module.
Power	Add a **470uF capacitor** across VCC and GND to stabilize spikes.

Are you seeing the garbage values **only when you send a command**, or is the module **constantly printing junk** on its own?

rst:0x1 (POWERON_RESET),boot:0x17 (SPI_FAST_FLASH_BOOT)configsip: 0, ...

8 hours ago

Since your Serial Monitor is showing the **"Bridge Ready"** message clearly, the ESP32 is working fine, but the **A7670C is talking at a different speed** or lacks enough power.

Follow these steps in order to fix the garbage output:

1. The Baud Rate Fix (Most Likely)

The A7670C often ships with **"Auto-Bauding"** enabled, which fails when connected to an ESP32. It is likely trying to communicate at **9600** while your code is at **115200**.

Change this line in your code:

```cpp
simSerial.begin(9600, SERIAL_8N1, RXD2, TXD2);
```

Use code with caution.

Problem in between E
begin(115200 delay(500); r
Arduino
Issues Inte Module wit
Additional Int module oper
Stack Ov
Serial Mon Values on I
Serial Monito ESP32? Here
OceanLa

- **Upload** the code.
- **Open Serial Monitor** (Keep Serial Monitor at **115200**).
- Type `AT` and press Enter. If you get `OK`, the problem is solved.

2. The Power Spike Fix

If you see garbage values **only after the module tries to blink its "Net" LED**, the module is brown-out resetting.

- **The Symptom:** The A7670C draws a massive **2A burst** when it tries to find a cell tower. If you are powering it from the ESP32's 5V pin or a laptop USB, the voltage drops, the serial buffer corrupts, and it prints junk.
- **The Fix:** Use an **external 5V 2A power adapter**. Connect the Adapter's (−) to the ESP32 GND and the Adapter's (+) to the A7670C VCC.

3. Check for "Floating" Ground

If there isn't a solid **Common Ground**, the serial signals "float" and look like noise (garbage).

- **Verify:** Is there a physical wire connecting **GND** on the A7670C board to **GND** on the ESP32?

4. Swap RX/TX Pins

Sometimes the labels on breakout boards (TX/RX) refer to where they *should go* rather than what they *are*.

- Try swapping the wires on **GPIO 16** and **17**.

Quick Test

Once you change the code to **9600 baud**, try typing these two commands into the Serial Monitor:

1. `AT` (Should return `OK`)
2. `AT+IPR=115200` (This forces the module to 115200 permanently so it matches your ESP32's high speed).

Did changing the `simSerial.begin` to **9600** change the look of the **garbage characters** at all?

rst:0x1 (POWERON_RESET),boot:0x17
(SPI_FAST_FLASH_BOOT)configsip: 0, ...

8 hours ago

That output confirms your **ESP32** is fine, but the **A7670C** is talking at a different speed than your code expects. Since you see `Bridge Ready` clearly, your PC-to-ESP32 connection is perfect.

The issue is the `simSerial.begin(115200...)` line. A7670C modules often ship at **9600** or have "Auto-Baud" enabled which glitches on ESP32 boot.

Step 1: Change the Code Baud Rate

Update your `setup()` to use **9600** for the module connection:

cpp

```cpp
void setup() {
  Serial.begin(115200); // Keep Serial Monitor at 115200

  // Change ONLY this line to 9600
  simSerial.begin(9600, SERIAL_8N1, RXD2, TXD2);

  Serial.println("ESP32 & A7670C Bridge Ready (Testing 9600 baud).");
}
```

Use code with caution.

Step 2: Test These Commands

After uploading the 9600 baud code, type these into the Serial Monitor (make sure **"Both NL & CR"** is selected at the bottom):

1. Type `AT` and press Enter.
   - *If you get* `OK`*:* You found the right speed!
2. Type `AT+IPR=115200` and press Enter.
   - This forces the module to match your ESP32's high speed.
   - **Note:** After this command, you must change your code back to `simSerial.begin(115200...)` for it to work again.

Step 3: Check for Power "Looping"

If the garbage characters appear **every few seconds** without you typing anything, the module is rebooting.

- **The Cause:** The module needs **2 Amps** to start the cellular radio. If it doesn't get enough power, it crashes, restarts, and prints a "boot log" which looks like garbage if the baud rate is wrong.
- **The Fix:** Are you using an **external power adapter** (5V/2A) connected to the module? (Laptop USB ports cannot power this module reliably).

Did the text change at all after switching to 9600 baud?

even when I type AT there is no response

8 hours ago

If the module is powered but you get **no response** to `AT` after seeing garbage, it means the module is either **not truly "ON"** or there is a **wiring reversal** between the ESP32 and A7670C. Arduino Forum +1

1. The "PWRKEY" Pulse (Crucial)

The A7670C does not always turn on automatically when power is applied. It requires a manual "kickstart."

- **Manual Test:** Briefly connect the **PWRKEY pin to GND** for about **1.5 seconds**, then

release it.

- **The Sign of Life:** The **NETLIGHT LED** should start blinking. If this LED is off, the module's processor is not running, and it will never respond to `AT`. Arduino Forum +3

2. Confirm Serial Wiring (TX/RX Swap)

A common mistake is connecting TX to TX. Serial communication must be "criss-crossed." Arduino Forum

- **ESP32 GPIO 17 (TX2) → A7670C RXD**
- **ESP32 GPIO 16 (RX2) → A7670C TXD**
- **GND → GND** (The ESP32 and A7670C **must** share a ground wire). Arduino Forum +1

3. Identify the "Garbage" Source

Since you saw garbage before, the module *is* trying to send data. If it stops responding entirely now, try these fixes:

- **Reset the ESP32:** Sometimes the ESP32 serial buffer hangs. Press the **EN/RESET** button on the ESP32 after the module's NETLIGHT starts blinking.
- **Serial Monitor Settings:** Ensure the bottom-right of your Serial Monitor is set to **Both NL & CR** and **115200 Baud**.

4. Logic Level Warning

The A7670C chip uses **1.8V logic**.

- **If you have a bare module:** Connecting it directly to the 3.3V ESP32 pins can sometimes silence the communication or damage the pins.
- **If you have a Breakout Board:** Most breakout boards (like those from ADIY or Robocraze) include level shifters that make them 3.3V/5V compatible.

Try this Test Sequence:

1. Power the module (External 5V/2A).
2. Hold **PWRKEY to GND** for 2 seconds.
3. Wait for the **NETLIGHT** to start blinking.
4. Open the Serial Monitor and type `AT`.

Is the NETLIGHT LED currently blinking on your module?

Great news! Your **AT** and **+CSQ** responses prove that your wiring, power, and baud rate (115200) are now **perfect**. A signal of **24** is excellent.

Since you are using an **M2M SIM**, the next step is to configure the **APN** and check if the network accepts the SIM. M2M SIMs will usually not get an IP address until you manually set the APN.

1. M2M Network Test Sequence

Type these commands into your Serial Monitor one by one (or add them to your `if (input == 'S')` block):

Command	Expected Response	Purpose
`AT+CPIN?`	`+CPIN: READY`	Confirms SIM is unlocked and detected.
`AT+CREG?`	`+CREG: 0,1` or `0,5`	Confirms you are registered on the network.
`AT+CGDCONT=1,"IP","YOUR_APN"`	`OK`	**Crucial:** Replace `YOUR_APN` with the one from your M2M provider.
`AT+CGACT=1,1`	`OK`	Activates the data context.
`AT+CGPADDR=1`	`+CGPADDR: 1, 10.xxx.xx.xx`	Returns your M2M IP address.

2. Updated Code for M2M Activation

You can replace your `if (input == 'S')` block with this sequence to automate the M2M login:

cpp

```cpp
if (input == 'S') {
  // 1. Check SIM
  Serial2.println("AT+CPIN?");
  delay(1000);
  waitForResponse();

  // 2. Set M2M APN (Change "://t-mobile.com" to your actual APN)
  Serial2.println("AT+CGDCONT=1,\"IP\",\"://t-mobile.com\"");
  delay(1000);
  waitForResponse();

  // 3. Attach to GPRS/LTE
  Serial2.println("AT+CGATT=1");
  delay(2000);
  waitForResponse();

  // 4. Check assigned IP
  Serial2.println("AT+CGPADDR=1");
  delay(1000);
  waitForResponse();
}
```

Use code with caution.

3. Pro-Tips for M2M SIMs

- **Roaming:** Many M2M SIMs use roaming. If `AT+CREG?` returns `0,0`, try `AT+CREG=1` then check again.
- **Registration:** If you see `+CREG: 0,3` (Registration Denied), it usually means the APN is wrong or the SIM hasn't been activated by the provider yet.

Do you have the **APN name** from your SIM provider, or would you like a snippet to test a simple **HTTP GET** request now that you have a signal?

ATOKAT+CSQ+CSQ: 25,99OKAT+CPIN?+CPIN: READYOKAT+CREG?+CREG: ...

7 hours ago

For an **Airtel M2M (IoT) SIM** in India, the most common APN is `airteliot.com`. However, many Airtel enterprise accounts also use the standard public APN `airtelgprs.com`. Quectel Forums +2

Since your module already returned an IP address (`10.13.166.70`), it has actually **already successfully connected** to a default APN provided by the network. You may not need to manually set it, but it is good practice to define it for stability. Quectel Forums +1

1. Recommended Airtel APN Commands

Try setting the IoT-specific APN first. If it fails or you lose your IP, switch to the GPRS one.

- **Option A (IoT/M2M Specific):**
  `AT+CGDCONT=1,"IP","airteliot.com"`
- **Option B (Standard Public):**
  `AT+CGDCONT=1,"IP","airtelgprs.com"` Quectel Forums +3

2. Full Activation Sequence

Run these commands in order to ensure the data context is fully active with the new APN:

bash

```bash
AT+CFUN=1            # Ensure full functionality
AT+CGDCONT=1,"IP","airteliot.com"  # Set the APN
AT+CGACT=1,1         # Activate the context
AT+CGPADDR=1         # Verify your new IP address
```

Use code with caution.

3. Verification & Troubleshooting

- **Registration Status:** Your previous output `+CREG: 0,1` means you are registered on your home network. If it changes to `0,5`, you are roaming, which is common for M2M SIMs.
- **Ping Test:** Once you see the IP address again, you can test the actual internet connection by pinging Google's DNS:
  `AT+PING="8.8.8.8"`
- **Private APN:** If neither `airteliot.com` nor `airtelgprs.com` works for your specific business application, you must contact your **Airtel Enterprise coordinator**, as some M2M SIMs are locked to a **Private Static APN** unique to your company. Quectel Forums +2

Since you have an active IP address, would you like the code to **send a test sensor value to a server** or check your **remaining data balance**?

can I send data to blynk now?

7 hours ago

Yes, you can now send data to Blynk. Since your **A7670C** has an active IP address, it is ready to communicate with the Blynk Cloud. GitHub +3

1. Required Libraries

You need to install two libraries in your Arduino IDE: YouTube +2

- **Blynk**: To handle the IoT dashboard.
- **TinyGSM**: To allow the Blynk library to use your A7670C as the internet modem. GitHub +4

2. Blynk Code for A7670C + ESP32

Use this sketch as your new base. It uses the `TinyGsm` library to bridge the cellular connection to Blynk. GitHub +1

cpp

```cpp
// Template ID, Name, and Auth Token from Blynk Console
#define BLYNK_TEMPLATE_ID   "Your_Template_ID"
#define BLYNK_TEMPLATE_NAME "Your_Device_Name"
#define BLYNK_AUTH_TOKEN    "Your_Auth_Token"

// Select your modem (A7670 is compatible with SIM7600 commands)
#define TINY_GSM_MODEM_SIM7600
#define BLYNK_PRINT Serial

#include <TinyGsmClient.h>
#include <BlynkSimpleTinyGSM.h>

// Your Airtel M2M APN
const char apn[]  = "airteliot.com";
const char user[] = "";
const char pass[] = "";

// ESP32 Hardware Serial 2 pins
#define RXD2 16
#define TXD2 17

HardwareSerial simSerial(2);
TinyGsm modem(simSerial);

void setup() {
  Serial.begin(115200);

  // Initialize A7670C
  simSerial.begin(115200, SERIAL_8N1, RXD2, TXD2);
  delay(3000);

  Serial.println("Connecting to Blynk...");
  // This command handles the APN login and Blynk connection
  Blynk.begin(BLYNK_AUTH_TOKEN, modem, apn, user, pass);
}

void loop() {
  Blynk.run();
}
```

Use code with caution

3. Key Setup Steps

1. **Blynk Template**: In the Blynk Web Console, create a new **Template**.
2. **Hardware Selection**: Set the hardware to **ESP32** and connection type to **GSM** (or choose WiFi if GSM isn't listed; the code handles the actual link).
3. **Auth Token**: Copy the **Auth Token** from the "Device Info" tab and paste it into the code above.
4. **APN**: If `airteliot.com` doesn't work, try leaving it blank (`""`) as some 4G SIMs auto-detect the settings. YouTube +4

4. Sending a Test Value

To send a number (like a sensor value) to a **Virtual Pin (V1)**, add this inside your `loop()` or use a timer: YouTube +2

```cpp
Blynk.virtualWrite(V1, 42); // Sends the value 42 to Virtual Pin 1
```

Use code with caution.

Would you like help setting up a **Blynk Timer** to send data every 10 seconds without crashing the connection?

I have a ds18b20 température sensor and I need to send its data

7 hours ago

To send **DS18B20** temperature data to **Blynk** via your **A7670C**, you need to **add the DallasTemperature and OneWire libraries to your ESP32 setup**. Random Nerd Tutorials +1

1. Wiring Connections

The DS18B20 usually has three wires: **Red (VCC)**, **Black (GND)**, and **Yellow/White (Data)**. YouTube

DS18B20 Wire	ESP32 Pin	Notes
VCC (Red)	**3.3V**	Powers the sensor
GND (Black)	**GND**	Common ground with ESP32 and A7670C
Data (Yellow)	**GPIO 4**	Can use other pins like GPIO 13 or 14

Important: You must place a **4.7kΩ resistor** between the **Data** wire and **3.3V** (Pull-up resistor) for the sensor to work. YouTube +1

2. Complete Code for A7670C + DS18B20 + Blynk

This code reads the temperature every 10 seconds and sends it to Blynk Virtual Pin **V1**.

#define BLYNK_TEMPLATE_ID   "Your_Template_ID"
#define BLYNK_TEMPLATE_NAME "Your_Device_Name"
#define BLYNK_AUTH_TOKEN    "Your_Auth_Token"

#define TINY_GSM_MODEM_SIM7600 // A7670 is compatible with SIM7600
#include <TinyGsmClient.h>
#include <BlynkSimpleTinyGSM.h>
#include <OneWire.h>
#include <DallasTemperature.h>

// Pins and APN
#define SENSOR_PIN 4
#define RXD2 16
#define TXD2 17
const char apn[] = "airteliot.com"; // Use your verified APN

HardwareSerial simSerial(2);
TinyGsm modem(simSerial);
OneWire oneWire(SENSOR_PIN);
DallasTemperature sensors(&oneWire);
BlynkTimer timer;

void sendSensorData() {
  sensors.requestTemperatures();
  float tempC = sensors.getTempCByIndex(0);

  if (tempC != DEVICE_DISCONNECTED_C) {
    Blynk.virtualWrite(V1, tempC); // Send to Blynk Virtual Pin V1
    Serial.print("Temperature sent: ");
    Serial.println(tempC);

  } else {
    Serial.println("Error: Could not read temperature");
  }
}

void setup() {
  Serial.begin(115200);
  simSerial.begin(115200, SERIAL_8N1, RXD2, TXD2);
  delay(3000);

  sensors.begin(); // Initialize DS18B20

  Blynk.begin(BLYNK_AUTH_TOKEN, modem, apn, "", "");

  // Set a timer to send data every 10 seconds
  timer.setInterval(10000L, sendSensorData);
}

void loop() {
  Blynk.run();
  timer.run();
}
```

Use code with caution.

3. Blynk App Setup

1. Open your **Blynk Console** or Mobile App.
2. Go to **Datastreams** and create a new **Virtual Pin** datastream.
3. Set it to **V1**, Name: `Temperature`, Data Type: `Double`, and Unit: `°C`.

4. Add a **Gauge** or **Label** widget to your dashboard and link it to the `Temperature` datastream. YouTube +2

If the sensor returns `-127`, it usually means the **4.7kΩ resistor** is missing or the **wiring** to the data pin is loose. Blynk Community

Do you have the **4.7kΩ resistor** ready, or do you need a way to test the sensor without one?

how-to-int
temperatu
Therefore, yo
using a 3.3V
Matha E

serial monitor is blank and the dashboard is also not showing anything

7 hours ago

If the Serial Monitor is completely blank, it means the code is hanging during the `Blynk.begin` phase, which is common if the modem doesn't respond instantly or the APN is slightly off.

To fix this, we need to add more "Serial.print" debug lines and a small hardware reset for the modem.

1. Update the Code for Debugging

Replace your `setup()` with this version. It adds a "Wake Up" pulse and prints status messages so we can see exactly where it stops.

cpp

```cpp
void setup() {
  Serial.begin(115200);
  delay(1000);
  Serial.println("--- System Starting ---");

  // Initialize A7670C Serial
  simSerial.begin(115200, SERIAL_8N1, 16, 17);
  delay(3000);

  // Optional: Wake up the module if it's sleeping
  Serial.println("Waking up modem...");
  simSerial.println("AT");
  delay(500);

  sensors.begin();
  Serial.println("DS18B20 Initialized.");

  Serial.println("Connecting to Blynk (This may take 30 seconds)...");

  // Use a blank APN "" first if airteliot.com hangs
  Blynk.begin(BLYNK_AUTH_TOKEN, modem, "airteliot.com", "", "");

  Serial.println("Blynk Connected!");
  timer.setInterval(10000L, sendSensorData);
}
```

Use code with caution.

2. Common Fixes for "Blank" Serial Monitor

- **Wrong Pins:** Double-check your code: `simSerial.begin(115200, SERIAL_8N1, 16, 17);`. If your wires are on 16/17, make sure they aren't swapped (**TX to RX**, **RX to TX**).
- **Power:** If the module tries to connect to the internet, it pulls a lot of current. If the ESP32 doesn't have enough power, it might **freeze** or **reboot** before it can print anything. Use an external 5V/2A power source.
- **Baud Rate:** Ensure the **Serial Monitor** (bottom right of Arduino IDE) is set to **115200**.

3. Check the "Ready" LED

Is the **NETLIGHT** on the A7670C blinking?

- **Fast blink:** Searching for network.
- **Slow blink (once every 3 seconds):** Registered on 4G.
- **Off:** The module is powered off. (Hold **PWRKEY to GND** for 2 seconds to start it).

4. M2M APN Issue

If it hangs at "Connecting to Blynk," try changing the APN line to:
`Blynk.begin(BLYNK_AUTH_TOKEN, modem, "", "", "");`
(Airtel M2M often auto-authenticates if the APN is left blank).

Does the Serial Monitor show "--- System Starting ---" after you press the RESET button on the ESP32?

give the entire code

7 hours ago

To ensure this works, I have added **Serial Debugging** throughout the code. This will tell us exactly where it stops (e.g., if it's stuck at the Sensor, the Modem, or the Blynk connection).

Prerequisites

1. **Libraries:** Install `Blynk`, `TinyGSM`, `OneWire`, and `DallasTemperature` via the Library Manager.
2. **Blynk Info:** Fill in your Template ID and Auth Token.
3. **Hardware:** Ensure **GPIO 4** has the DS18B20 with a **4.7k resistor** to 3.3V.

cpp

```cpp
// 1. Blynk Cloud Settings
#define BLYNK_TEMPLATE_ID   "Your_Template_ID"
#define BLYNK_TEMPLATE_NAME "Your_Device_Name"
#define BLYNK_AUTH_TOKEN    "Your_Auth_Token"

// 2. Modem Settings (A7670C uses SIM7600 commands)
#define TINY_GSM_MODEM_SIM7600
#define BLYNK_PRINT Serial // This enables Blynk debug prints in Serial M

#include <TinyGsmClient.h>
#include <BlynkSimpleTinyGSM.h>
#include <OneWire.h>
#include <DallasTemperature.h>
```

```
// 3. Hardware Pins
#define SENSOR_PIN 4
#define RXD2 16
#define TXD2 17

// 4. Network Settings (Airtel M2M)
const char apn[]  = "airteliot.com"; // Try "" if this fails
const char user[] = "";
const char pass[] = "";

HardwareSerial simSerial(2);
TinyGsm modem(simSerial);
OneWire oneWire(SENSOR_PIN);
DallasTemperature sensors(&oneWire);
BlynkTimer timer;

// Function to read sensor and send to Blynk
void sendSensorData() {
  Serial.println("Reading temperature...");
  sensors.requestTemperatures();
  float tempC = sensors.getTempCByIndex(0);

  if (tempC != DEVICE_DISCONNECTED_C) {
    Serial.print("Temp: ");
    Serial.print(tempC);
    Serial.println(" C. Sending to Blynk...");
    Blynk.virtualWrite(V1, tempC); // Virtual Pin V1
  } else {
    Serial.println("Error: DS18B20 not found! Check wiring/resistor.");
  }
}

void setup() {
  // Set console baud rate
  Serial.begin(115200);
  delay(1000);
  Serial.println("\n--- SYSTEM STARTING ---");

  // Initialize A7670C
  Serial.println("Initializing modem Serial2...");

  simSerial.begin(115200, SERIAL_8N1, RXD2, TXD2);
  delay(3000);

  // Initialize DS18B20
  sensors.begin();
  Serial.println("DS18B20 Initialized.");

  // Check if modem is responding
  Serial.println("Checking modem communication...");
  if (!modem.testAT()) {
    Serial.println("Failed to connect to modem! Check wiring/power.");
    // Optional: Pulse PWRKEY here if your board supports it
  } else {
    Serial.println("Modem OK.");
  }

  // Connect to Blynk
  Serial.println("Connecting to Blynk (This can take 20-40 seconds)...");
  Blynk.begin(BLYNK_AUTH_TOKEN, modem, apn, user, pass);

  if (Blynk.connected()) {
    Serial.println("Blynk Connected Successfully!");
  }

  // Setup timer to send data every 10 seconds
```

```
  timer.setInterval(10000L, sendSensorData);
}

void loop() {
  Blynk.run();
  timer.run();
}
```

Use code with caution.

If Serial Monitor is still blank:

1. **Press the EN/RESET button** on your ESP32 after uploading.
2. **Check Serial Monitor Baud:** Must be set to **115200**.
3. **Check RX/TX:** Ensure ESP32 **TX2 (17)** goes to A7670C **RX** and ESP32 **RX2 (16)** goes to A7670C **TX**.
4. **A7670C Power:** If the **NETLIGHT** isn't blinking, the module is off. Pulse **PWRKEY to GND** for 2 seconds.

Does the Serial Monitor now show "--- SYSTEM STARTING ---" when you reset the ESP32?

--- SYSTEM STARTING ---Initializing modem Serial2...DS18B20 Initialized.Checking modem ...

7 hours ago

The log `Failed to connect to modem!` means the ESP32 is sending "AT" but the A7670C is not answering. This is why it hangs at the Blynk logo—it's waiting for a response that never comes.

Since your previous manual test worked, we just need to fix the **startup timing** and **pins**.

1. The "Wake Up" Pulse

Most A7670C boards need the **PWRKEY** pin pulled to **GND** for 2 seconds to turn on. If the LEDs aren't blinking, the modem is "asleep."

Physical Fix: Take a jumper wire and touch the **PWRKEY** pin on the A7670C to a **GND** pin for 2 seconds. The **NETLIGHT** should start blinking.

2. Check Pin Assignment

In your successful manual test, you used `Serial2.begin(115200, SERIAL_8N1, 17, 16)`.

In the Blynk code, it was `(115200, SERIAL_8N1, 16, 17)`.

Swap them back to match your working test:
Change this line in `setup()`:

```cpp
simSerial.begin(115200, SERIAL_8N1, 17, 16); // Match your working test p
```

Use code with caution.

3. Updated `setup()` with Auto-Power

Add this block to the very top of your `setup()` to "kickstart" the module automatically:

cpp

```cpp
#define PWR_KEY_PIN 4 // Connect ESP32 Pin 4 to A7670C PWRKEY (if availab

void setup() {
  Serial.begin(115200);
  delay(1000);
  Serial.println("\n--- SYSTEM STARTING ---");

  // Power On Sequence
  pinMode(PWR_KEY_PIN, OUTPUT);
  digitalWrite(PWR_KEY_PIN, LOW);
  delay(2000); // Hold for 2 seconds
  digitalWrite(PWR_KEY_PIN, HIGH);
  Serial.println("Pulse sent to PWRKEY.");
  delay(5000); // Give the module 5 seconds to boot up

  simSerial.begin(115200, SERIAL_8N1, 17, 16); // Use your working pins
  // ... rest of the code
}
```

Use code with caution.

Immediate Check:

1. Is the **NETLIGHT** (or "Network") LED blinking on the A7670C?
2. If **No**: Your module is off. Connect **PWRKEY to GND** for 2 seconds.
3. If **Yes (Blinking)**: Swap the wires on ESP32 Pins **16 and 17** and press Reset.

After you swap pins 16 and 17, does it still say "Failed to connect to modem"?

--- SYSTEM STARTING ---Initializing modem Serial2...DS18B20 Initialized.Checking modem ...

7 hours ago

The error `[24448] Cannot init` combined with `Failed to connect to modem!` means the ESP32 is correctly trying to start the Blynk process, but the A7670C is not responding to its internal "wake up" commands. This usually happens because the modem is either powered off or the Serial pins are still not aligned with the TinyGSM library's expectations. Reddit +3

1. The "Final Fix" Checklist

- **Physical Power:** Is the **NETLIGHT** LED blinking? If not, the module is OFF. You **must**

hold the **PWRKEY** to GND for 2 seconds to turn it on.

- **Serial Swap:** In your previous successful test, you used `(17, 16)`. The code below is strictly set to those pins.
- **Blynk Server:** Sometimes Blynk hangs on GSM if the port/server isn't explicitly defined. I've added the explicit "blynk.cloud" address to the `Blynk.begin` command. Reddit +4

2. Complete Integrated Code

Replace your entire script with this version. I have added a `restartModem()` function to force the A7670C to respond.

cpp

```cpp
#define BLYNK_TEMPLATE_ID   "Your_Template_ID"
#define BLYNK_TEMPLATE_NAME "Your_Device_Name"
#define BLYNK_AUTH_TOKEN    "Your_Auth_Token"

// Modem Configuration
#define TINY_GSM_MODEM_SIM7600  // A7670C is compatible with SIM7600
#define BLYNK_PRINT Serial

#include <TinyGsmClient.h>
#include <BlynkSimpleTinyGSM.h>
#include <OneWire.h>
#include <DallasTemperature.h>

// Pins
#define SENSOR_PIN 4
#define RXD2 17  // Match your working test
#define TXD2 16  // Match your working test

// Network
const char apn[] = "airteliot.com"; // Airtel M2M APN

HardwareSerial simSerial(2);
TinyGsm modem(simSerial);
OneWire oneWire(SENSOR_PIN);
DallasTemperature sensors(&oneWire);
BlynkTimer timer;

void sendSensorData() {
  sensors.requestTemperatures();
  float tempC = sensors.getTempCByIndex(0);
  if (tempC != DEVICE_DISCONNECTED_C) {
    Blynk.virtualWrite(V1, tempC);
    Serial.printf("Temperature: %.2f C\n", tempC);
  }
}

void setup() {
  Serial.begin(115200);
  delay(1000);
  Serial.println("\n--- HARDWARE INITIALIZING ---");

  // Start Modem Serial
  simSerial.begin(115200, SERIAL_8N1, RXD2, TXD2);
  delay(3000);

  // Force Modem Response
  Serial.println("Checking Modem...");
  int retry = 0;
  while (!modem.testAT() && retry < 5) {
    Serial.println("Modem not responding. Retrying...");
    delay(2000);
```

```
    retry++;
  }

  sensors.begin();

  // Explicit Blynk Connection for GSM
  Serial.println("Connecting to Blynk Cloud...");
  Blynk.begin(BLYNK_AUTH_TOKEN, modem, apn, "", "", "blynk.cloud", 80);

  timer.setInterval(10000L, sendSensorData);
}

void loop() {
  Blynk.run();
  timer.run();
}
```

Use code with caution.

3. Troubleshooting the "Cannot Init"

1. **Check Power:** If you are powering the A7670C from the ESP32's 5V pin, it will fail during the Blynk connection because the modem draws **2A** when transmitting data. Use a dedicated power adapter.
2. **Logic Levels:** If your A7670C is a bare module, it uses **1.8V logic**. Connecting it directly to the ESP32's **3.3V pins** can cause communication to fail.
3. **Manual Start:** If you see `Modem not responding` in the Serial Monitor, **manually** touch the **PWRKEY pin to GND** for 2 seconds while the code is running. Arduino Forum +3

Does the Serial Monitor now show "Temperature sent" or does it still stop at "Modem not responding"?

the led is blinking

7 hours ago

Since the **NETLIGHT** is blinking, the module is definitely powered on and registered. The "Cannot init" error with a blinking LED almost always means the **TinyGSM library** is sending commands faster than the A7670C can process them or the Serial pins are slightly mismatched for the library's specific timing. GitHub +3

1. Final Verified Code for A7670C + Blynk

This version includes a **slower modem initialization** and a specific fix for the Serial buffer that often causes the "Cannot init" hang on ESP32. GitHub

cpp

```
#define BLYNK_TEMPLATE_ID   "Your_Template_ID"
#define BLYNK_TEMPLATE_NAME "Your_Device_Name"
#define BLYNK_AUTH_TOKEN    "Your_Auth_Token"

// Modem and Debugging
#define TINY_GSM_MODEM_SIM7600 // A7670C is compatible with SIM7600
```

#include <TinyGsmClient.h>
#include <BlynkSimpleTinyGSM.h>
#include <OneWire.h>
#include <DallasTemperature.h>

// Pins: Match your working 'AT' test
#define RXD2 17
#define TXD2 16
#define SENSOR_PIN 4

// Network: Airtel M2M
const char apn[] = "airteliot.com";

HardwareSerial simSerial(2);
TinyGsm modem(simSerial);
OneWire oneWire(SENSOR_PIN);
DallasTemperature sensors(&oneWire);
BlynkTimer timer;

void sendSensorData() {
  sensors.requestTemperatures();
  float tempC = sensors.getTempCByIndex(0);
  if (tempC != DEVICE_DISCONNECTED_C) {
    Blynk.virtualWrite(V1, tempC);
    Serial.printf("Temperature: %.2f C sent to Blynk\n", tempC);
  }
}

void setup() {
  Serial.begin(115200);
  delay(1000);
  Serial.println("\n--- STARTING BLYNK INTERFACE ---");

  // Initialize HardwareSerial2 with a small delay for stability
  simSerial.begin(115200, SERIAL_8N1, RXD2, TXD2);
  delay(5000); // Wait for module to stabilize after power-on

  sensors.begin();

  // Connect to Blynk with explicit server settings
  Serial.println("Initializing modem and connecting to Blynk...");

  // If "airteliot.com" fails, try leaving APN as ""
  Blynk.begin(BLYNK_AUTH_TOKEN, modem, apn, "", "", "blynk.cloud", 80);

  timer.setInterval(10000L, sendSensorData);
}

void loop() {
  Blynk.run();
  timer.run();
}
```

Use code with caution.

2. Why it "Cannot Init" (Solutions)

- **Buffer Overload:** The ESP32 is much faster than the A7670C. If the library doesn't get an immediate "OK," it assumes failure. The `delay(5000)` in `setup()` helps the module finish its internal boot-up before the library starts "spamming" commands.
- **APN Conflict:** If the Serial Monitor hangs at `Modem init...`, try changing the

8

SIM A7670
Board – Co

`Blynk.begin` line to use an empty APN: `Blynk.begin(BLYNK_AUTH_TOKEN, modem, "", "", "", "blynk.cloud", 80);`.

- **Airtel M2M Tip:** Ensure your SIM has an active data plan. If the LED blinks **slowly** (once every 3 seconds), you have a data connection. If it blinks **quickly** (twice a second), it is still searching for a network and Blynk will fail to init. GitHub +6

3. Hardware Check

- **Common Ground:** Double-check that a wire connects the **GND** of the A7670C directly to the **GND** of the ESP32.
- **Power Supply:** If you are using a USB cable for power, the 4G transmission burst might be dropping the voltage just enough to crash the Serial communication while leaving the LED blinking. Arduino Forum +1

Is the LED blinking slowly (every 3 seconds) or quickly (every 0.5 seconds)?

lets remove the temprature sensor just send a simple text to display on the blynk dashboard

7 hours ago

This simplified code removes the sensor and sends a fixed text string like **"A7670C Online"** to your Blynk dashboard every 10 seconds. Blynk Community

1. Blynk Dashboard Setup

Before uploading, you must prepare the widget to receive text:

- **Create Datastream**: In your Blynk Template, add a new **Virtual Pin** datastream.
- **Settings**: Set it to **V1**, Data Type to **String**.
- **Add Widget**: Add a **Label** or **Value Display** widget to your dashboard and link it to **V1**. Blynk +4

2. Simple Text Code

cpp

```cpp
#define BLYNK_TEMPLATE_ID   "Your_Template_ID"
#define BLYNK_TEMPLATE_NAME "Your_Device_Name"
#define BLYNK_AUTH_TOKEN    "Your_Auth_Token"

#define TINY_GSM_MODEM_SIM7600
#define BLYNK_PRINT Serial

#include <TinyGsmClient.h>
#include <BlynkSimpleTinyGSM.h>

// Pins: Match your working 'AT' test
#define RXD2 17
#define TXD2 16

const char apn[] = "airteliot.com";

HardwareSerial simSerial(2);
TinyGsm modem(simSerial);
BlynkTimer timer;
```

Powering the A7670C
Yarana
Problem c SIM7000C
// communica using modem
GitHub
[M590] LIb ESP32 #91
Description. #81, using Ha
GitHub

```
BlynkTimer timer;

void sendSimpleText() {
  // Sending a simple string to Virtual Pin V1
  String statusMsg = "A7670C System OK";
  Blynk.virtualWrite(V1, statusMsg);
  Serial.println("Sent: " + statusMsg);
}

void setup() {
  Serial.begin(115200);
  delay(1000);
  Serial.println("\n--- BLYNK TEXT TEST ---");

  simSerial.begin(115200, SERIAL_8N1, RXD2, TXD2);
  delay(5000);

  // Initialize modem and connect
  Blynk.begin(BLYNK_AUTH_TOKEN, modem, apn, "", "", "blynk.cloud", 80);

  // Timer to send text every 10 seconds
  timer.setInterval(10000L, sendSimpleText);
}

void loop() {
  Blynk.run();
  timer.run();
}
```

Use code with caution.

Why this is better for testing:

- **No Hardware Failure**: By removing the DS18B20, we eliminate errors caused by missing resistors or loose wires.
- **Direct String Testing**: Using `Blynk.virtualWrite(V1, "string")` is the most reliable way to confirm the 4G data link is actually pushing data to the cloud.
- **Faster Debugging**: If "Sent: A7670C System OK" appears in your Serial Monitor but not on the dashboard, you know the issue is just the **Datastream setting** in Blynk, not your hardware. Blynk +1

Does "Sent: A7670C System OK" appear in your Serial Monitor now?

now lets add the temprature sensors data stream and send its data to what do I need to add to the code

4 hours ago

To add the **DS18B20** back into your working text code, you need to add the **DallasTemperature library components** and update your sending function.

1. What to Add to the Code

You need to add these **four** sections to your current simplified text code:

A. Add the Libraries (at the top):

8 sit
Value Disp
Documenta
Displays the
value format
Blynk
Widgets no
Blynk Com
yet you've ch
"Need help...
Blynk Co
Text Input
Displays the
string value,
Blynk

```cpp
#include <OneWire.h>
#include <DallasTemperature.h>
```

Use code with caution.

B. Define the Sensor Pin and Objects (before `setup`):

```cpp
#define SENSOR_PIN 4  // Pin where your DS18B20 data wire is connected
OneWire oneWire(SENSOR_PIN);
DallasTemperature sensors(&oneWire);
```

Use code with caution.

C. Initialize the Sensor (inside `setup`):

```cpp
sensors.begin(); // Start the DS18B20 library
```

Use code with caution.

D. Update the Sending Function:
Replace your `sendSimpleText()` function with this one:

```cpp
void sendSensorData() {
  sensors.requestTemperatures();
  float tempC = sensors.getTempCByIndex(0);

  if (tempC != DEVICE_DISCONNECTED_C) {
    // Send to Virtual Pin V1 (Make sure V1 is set to Double/Float in Bly
    Blynk.virtualWrite(V1, tempC);
    Serial.print("Temperature sent: ");
    Serial.println(tempC);
  } else {
    Serial.println("Error: Sensor not found! Check 4.7k resistor.");
  }
}
```

Use code with caution.

2. Required Hardware Reminder

For the sensor to communicate correctly while the GSM module is active:

- **Pull-up Resistor:** Ensure a **4.7k ohm resistor** is connected between the DS18B20 **Data pin (GPIO 4)** and **3.3V**. Without this, you will get an "Error: Sensor not found" or a reading of `-127`.
- **Ground:** Ensure the sensor, ESP32, and A7670C all share a **Common Ground**.

3. Blynk Dashboard Change

Ensure your **Datastream for V1** in the Blynk Console is changed from **String** to **Double**

(or Integer) so it can display the numeric temperature correctly on a Gauge or Chart widget.

Do you have the **DallasTemperature** library installed in your Arduino IDE, or do you need the **full combined code** one last time?

/private/var/folders/q7/mk8hybvx5rxdrvzgjyv0ktwc0000gn/T/.arduinoIDE-unsaved202634-69656-...

4 hours ago

This error means you are either missing the `#include` lines at the very top of your code, or the libraries aren't actually installed in your Arduino IDE.

1. Fix the Libraries

Go to **Sketch** > **Include Library** > **Manage Libraries...** and search for/install these two:

1. **OneWire** (by Paul Stoffregen)
2. **DallasTemperature** (by Miles Burton)

2. The Complete Working Code

I have combined everything into one single file. Replace your **entire sketch** with this to ensure the headers are in the right order.

cpp

```cpp
#define BLYNK_TEMPLATE_ID   "Your_Template_ID"
#define BLYNK_TEMPLATE_NAME "Your_Device_Name"
#define BLYNK_AUTH_TOKEN    "Your_Auth_Token"

#define TINY_GSM_MODEM_SIM7600
#define BLYNK_PRINT Serial

#include <TinyGsmClient.h>
#include <BlynkSimpleTinyGSM.h>
#include <OneWire.h>           // MUST BE AT THE TOP
#include <DallasTemperature.h> // MUST BE AT THE TOP

// Hardware Pins
#define RXD2 17
#define TXD2 16
#define SENSOR_PIN 4

// Network Settings
const char apn[] = "airteliot.com";

// Objects
HardwareSerial simSerial(2);
TinyGsm modem(simSerial);
OneWire oneWire(SENSOR_PIN);
DallasTemperature sensors(&oneWire);
BlynkTimer timer;

void sendSensorData() {
  Serial.println("Requesting temperatures...");
```

```
  sensors.requestTemperatures();
  float tempC = sensors.getTempCByIndex(0);

  if (tempC != DEVICE_DISCONNECTED_C) {
    Blynk.virtualWrite(V1, tempC);
    Serial.print("Temp Sent: ");
    Serial.print(tempC);
    Serial.println(" C");
  } else {
    Serial.println("Error: DS18B20 not found! Check wiring and 4.7k resist
  }
}

void setup() {
  Serial.begin(115200);
  delay(1000);
  Serial.println("\n--- STARTING SYSTEM ---");

  // Start Modem Serial
  simSerial.begin(115200, SERIAL_8N1, RXD2, TXD2);
  delay(5000);

  // Initialize Sensor
  sensors.begin();
  Serial.println("Sensor Initialized.");

  // Connect to Blynk
  Serial.println("Connecting to Blynk Cloud...");
  Blynk.begin(BLYNK_AUTH_TOKEN, modem, apn, "", "", "blynk.cloud", 80);

  // Send data every 10 seconds
  timer.setInterval(10000L, sendSensorData);
}

void loop() {
  Blynk.run();
  timer.run();
}
```

Use code with caution.

Why the error happened:

The compiler didn't see the `#include <OneWire.h>` or `#include <DallasTemperature.h>` lines at the top of your file. Without those lines, the code doesn't know what a `OneWire` or `DallasTemperature` object is.

Does this code compile successfully now?

#define BLYNK_TEMPLATE_ID "TMPL3zOOuMdNy"#define BLYNK_TEMPLATE_NAME "try01"#define ...

3 hours ago

The reason your **Gauge** is not updating is because of a small mismatch in your code logic: your `timer` is calling `sendSimpleText` (which sends to **V1**), but your temperature logic is

inside `sendSensorData` (which sends to **V2**), and that function is **never being called**.

Also, ensure your **Blynk Gauge** is linked to **V2** (Double/Float) and your **Label/Value Display** is linked to **V1** (String).

The Fix

Update your `setup()` to include a timer for the sensor data. I've cleaned up the code below so both run correctly:

cpp

```cpp
#define BLYNK_TEMPLATE_ID "TMPL3z0OuMdNy"
#define BLYNK_TEMPLATE_NAME "try01"

#define BLYNK_AUTH_TOKEN "Wf5Ze5ZhyWuGEa_qNFpVUaLR4v_r_Acj"

#define TINY_GSM_MODEM_SIM7600
#define BLYNK_PRINT Serial

#include <OneWire.h>
#include <DallasTemperature.h>
#include <TinyGsmClient.h>
#include <BlynkSimpleTinyGSM.h>

// Pins
#define SENSOR_PIN 4
#define RXD2 17
#define TXD2 16

const char apn[] = "airteliot.com";

HardwareSerial simSerial(2);
TinyGsm modem(simSerial);
OneWire oneWire(SENSOR_PIN);
DallasTemperature sensors(&oneWire);
BlynkTimer timer;

// This sends text to V1
void sendSimpleText() {
  Blynk.virtualWrite(V1, "A7670C Online");
  Serial.println("Sent: Status Message to V1");
}

// This sends Temp to V2 (Linked to your Gauge)
void sendSensorData() {
  sensors.requestTemperatures();
  float tempC = sensors.getTempCByIndex(0);

  if (tempC != DEVICE_DISCONNECTED_C) {
    Blynk.virtualWrite(V2, tempC); // <--- Gauge must be on V2
    Serial.print("Temperature sent to V2: ");
    Serial.println(tempC);
  } else {
    Serial.println("Error: Sensor not found! Check 4.7k resistor.");
  }

}

void setup() {
  Serial.begin(115200);
  delay(1000);

  sensors.begin();
  simSerial.begin(115200, SERIAL_8N1, RXD2, TXD2);
```

```
  Serial.println("\n--- BLYNK SYSTEM START ---");
  delay(5000);

  // Initialize modem and connect
  Blynk.begin(BLYNK_AUTH_TOKEN, modem, apn, "", "", "blynk.cloud", 80);

  // SET TIMERS FOR BOTH FUNCTIONS
  timer.setInterval(10000L, sendSimpleText); // Every 10s
  timer.setInterval(12000L, sendSensorData); // Every 12s (staggered)
}

void loop() {
  Blynk.run();
  timer.run();
}
```

Use code with caution.

Critical Checklist if Gauge stays at 0:

1. **Datastream V2**: Go to the Blynk Web Console -> Templates -> Datastreams. Ensure **V2** is created as a **Double** or **Integer**.
2. **Widget Link**: In the Web or Mobile Dashboard, click on your **Gauge** and make sure the "Datastream" is set to **V2**.
3. **Sensor Wiring**: If the Serial Monitor says **"Error: Sensor not found"**, your 4.7k resistor is likely missing or loose on Pin 4.

Does the Serial Monitor show "Temperature sent to V2" now?

now I want to add a sht45 sensor code too and display it on the dashboardboth reading of temprature and humidity seprately

2 hours ago

To add the **SHT4x (SHT45)** sensor, **you will need the Adafruit SHT4x library**. Since the SHT45 uses **I2C**, you must connect it to the ESP32's I2C pins.

1. Wiring Connections

SHT45 Pin	ESP32 Pin	Notes
VCC	**3.3V**	Powers the sensor
GND	**GND**	Common ground
SCL	**GPIO 22**	SCL (Standard I2C)
SDA	**GPIO 21**	SDA (Standard I2C)

2. Blynk Dashboard Setup

Create two new **Datastreams** in your Blynk Template:

1. **V3**: Name: `SHT45 Temperature`, Type: `Double`, Unit: `°C`.

2. **V4**: Name: `SHT45 Humidity`, Type: `Double`, Unit: `%`.

3. Integrated Code

This code now reads from **DS18B20** (V2) and **SHT45** (V3 & V4).

cpp

```cpp
#define BLYNK_TEMPLATE_ID "TMPL3z0OuMdNy"
#define BLYNK_TEMPLATE_NAME "try01"
#define BLYNK_AUTH_TOKEN "Wf5Ze5ZhyWuGEa_qNFpVUaLR4v_r_Acj"

#define TINY_GSM_MODEM_SIM7600
#define BLYNK_PRINT Serial

#include <Wire.h>
#include <Adafruit_SHT4x.h>
#include <OneWire.h>
#include <DallasTemperature.h>
#include <TinyGsmClient.h>
#include <BlynkSimpleTinyGSM.h>

// Pins
#define SENSOR_PIN 4  // DS18B20
#define RXD2 17
#define TXD2 16

const char apn[] = "airteliot.com";

HardwareSerial simSerial(2);
TinyGsm modem(simSerial);
OneWire oneWire(SENSOR_PIN);
DallasTemperature sensors(&oneWire);
Adafruit_SHT4x sht4 = Adafruit_SHT4x();
BlynkTimer timer;

void sendAllData() {
  // 1. Read DS18B20
  sensors.requestTemperatures();
  float dsTemp = sensors.getTempCByIndex(0);
  if (dsTemp != DEVICE_DISCONNECTED_C) {
    Blynk.virtualWrite(V2, dsTemp);
    Serial.printf("DS18B20 Temp: %.2f C\n", dsTemp);
  }

  // 2. Read SHT45
  sensors_event_t humidity, temp;
  sht4.getEvent(&humidity, &temp);

  Blynk.virtualWrite(V3, temp.temperature);
  Blynk.virtualWrite(V4, humidity.relative_humidity);

  Serial.printf("SHT45 Temp: %.2f C, Hum: %.2f %%\n", temp.temperature, hu
}

void setup() {
  Serial.begin(115200);
  delay(1000);

  // Initialize Sensors
  sensors.begin();
  if (!sht4.begin()) {
    Serial.println("Couldn't find SHT4x sensor!");
  } else {
    Serial.println("SHT4x Found!");
    sht4.setPrecision(SHT4X_HIGH_PRECISION);
```

```
  }

  simSerial.begin(115200, SERIAL_8N1, RXD2, TXD2);
  Serial.println("\n--- BLYNK MULTI-SENSOR START ---");
  delay(5000);

  Blynk.begin(BLYNK_AUTH_TOKEN, modem, apn, "", "", "blynk.cloud", 80);

  // Send all data every 15 seconds
  timer.setInterval(15000L, sendAllData);
}

void loop() {
  Blynk.run();
  timer.run();
}
```

Use code with caution.

Important Steps:

1. **Install Library**: Go to Library Manager and install **"Adafruit SHT4x"**.
2. **Check I2C Address**: The SHT45 is usually at `0x44`. If it's not found, run an I2C scanner sketch.
3. **Timing**: I changed the timer to **15 seconds** to prevent overwhelming the 4G connection with too many simultaneous writes.

Does the Serial Monitor show **"SHT4x Found!"** after you upload this?

/private/var/folders/q7/mk8hybvx5rxdrvzgjyv0ktwc0000gn/T/.arduinoIDE-unsaved202634-69656-...

2 hours ago

This error means the **Adafruit SHT4x** library is not installed in your Arduino IDE.

1. How to Fix the Error

1. In the Arduino IDE, go to **Sketch** > **Include Library** > **Manage Libraries...**
2. In the search bar, type **"Adafruit SHT4x"**.
3. Find the one by **Adafruit** and click **Install**.
4. **Important:** A popup will ask to install "Dependencies" (like *Adafruit BusIO* and *Adafruit Unified Sensor*). Click **"Install All"**.

2. Verified Full Code

I have added a small logic change: it now checks if the SHT45 is actually connected before trying to read it, preventing the code from "hanging" if the sensor is missing.

cpp

```
#define BLYNK_TEMPLATE_ID "TMPL3z0OuMdNy"
#define BLYNK_TEMPLATE_NAME "try01"
```

```
#define BLYNK_AUTH_TOKEN "Wf5Ze5ZhyWuGEa_qNFpVUaLR4v_r_Acj"

#define TINY_GSM_MODEM_SIM7600
#define BLYNK_PRINT Serial

#include <Wire.h>
#include <Adafruit_SHT4x.h>
#include <OneWire.h>
#include <DallasTemperature.h>
#include <TinyGsmClient.h>
#include <BlynkSimpleTinyGSM.h>

// Pins
#define SENSOR_PIN 4  // DS18B20
#define RXD2 17
#define TXD2 16

const char apn[] = "airteliot.com";

HardwareSerial simSerial(2);
TinyGsm modem(simSerial);
OneWire oneWire(SENSOR_PIN);
DallasTemperature sensors(&oneWire);
Adafruit_SHT4x sht4 = Adafruit_SHT4x();
BlynkTimer timer;

bool shtFound = false;

void sendAllData() {
  // 1. DS18B20 Reading (V2)
  sensors.requestTemperatures();
  float dsTemp = sensors.getTempCByIndex(0);
  if (dsTemp != DEVICE_DISCONNECTED_C) {
    Blynk.virtualWrite(V2, dsTemp);
    Serial.printf("DS18B20: %.2f C | ", dsTemp);
  }

  // 2. SHT45 Reading (V3 & V4)
  if (shtFound) {
    sensors_event_t humidity, temp;
    sht4.getEvent(&humidity, &temp);

    Blynk.virtualWrite(V3, temp.temperature);
    Blynk.virtualWrite(V4, humidity.relative_humidity);

    Serial.printf("SHT45 Temp: %.2f C, Hum: %.2f %%\n", temp.temperature,
  } else {
    Serial.println("SHT45 Not Connected.");
  }
}

void setup() {
  Serial.begin(115200);
  delay(1000);
  Serial.println("\n--- SYSTEM START ---");

  // Start I2C for SHT45
  Wire.begin();
  if (sht4.begin()) {
    Serial.println("SHT4x Sensor Found!");
    sht4.setPrecision(SHT4X_HIGH_PRECISION);
    shtFound = true;
  } else {
    Serial.println("Warning: SHT4x Sensor NOT found.");
  }
```

```
  sensors.begin();
  simSerial.begin(115200, SERIAL_8N1, RXD2, TXD2);
  delay(5000);

  Blynk.begin(BLYNK_AUTH_TOKEN, modem, apn, "", "", "blynk.cloud", 80);

  // Send everything every 10 seconds
  timer.setInterval(10000L, sendAllData);
}

void loop() {
  Blynk.run();
  timer.run();
}
```

Use code with caution.

3. Connection Checklist

- **VCC/GND**: To 3.3V and GND.
- **SDA**: Connect to ESP32 **GPIO 21**.
- **SCL**: Connect to ESP32 **GPIO 22**.
- **Blynk**: Ensure **V3** (Temp) and **V4** (Humidity) are set as **Double** in your Blynk Datastreams.

Does the code **compile** now after installing the library?

now I need to add fluid level controller too

2 hours ago

To add a **fluid level controller**, the most common and reliable method is **using an HC-SR04 ultrasonic sensor**. It measures the distance to the liquid surface and calculates the percentage or volume.

1. Wiring Connections

Connect the HC-SR04 to your ESP32 as follows:

VCC **VIN (5V)**	VCC Needs 5V for accurate range
GND **GND**	GND Common ground with other modules
Trig **GPIO 5**	Trig Trigger signal (Output)
Echo **ESP32 Pin**	Echo **Notes**

2. Blynk Dashboard Setup

Add a new **Datastream** in your Blynk Template:

- **V5**: Name: `Fluid Level`, Type: `Integer` (0-100) for percentage.
- **Widget**: Use a **Level Widget** or **Gauge** linked to **V5**.

3. Integrated Full Code

This code now manages the **A7670C (GSM)**, **DS18B20**, **SHT45**, and the **HC-SR04**.

cpp

```cpp
#define BLYNK_TEMPLATE_ID "TMPL3z0OuMdNy"
#define BLYNK_TEMPLATE_NAME "try01"
#define BLYNK_AUTH_TOKEN "Wf5Ze5ZhyWuGEa_qNFpVUaLR4v_r_Acj"

#define TINY_GSM_MODEM_SIM7600
#define BLYNK_PRINT Serial

#include <Wire.h>
#include <Adafruit_SHT4x.h>
#include <OneWire.h>
#include <DallasTemperature.h>
#include <TinyGsmClient.h>
#include <BlynkSimpleTinyGSM.h>

// Pins
#define SENSOR_PIN 4    // DS18B20
#define TRIG_PIN 5      // Ultrasonic Trig
#define ECHO_PIN 18     // Ultrasonic Echo
#define RXD2 17         // GSM RX
#define TXD2 16         // GSM TX

// Tank Dimensions (Measure in cm)
const int TANK_HEIGHT = 100; // Distance from sensor to empty bottom
const int FULL_LEVEL = 10;   // Distance from sensor to full water line

const char apn[] = "airteliot.com";

HardwareSerial simSerial(2);
TinyGsm modem(simSerial);
OneWire oneWire(SENSOR_PIN);
DallasTemperature sensors(&oneWire);
Adafruit_SHT4x sht4 = Adafruit_SHT4x();
BlynkTimer timer;

bool shtFound = false;

void sendAllData() {
  // 1. DS18B20 (V2)
  sensors.requestTemperatures();
  float dsTemp = sensors.getTempCByIndex(0);
  if (dsTemp != DEVICE_DISCONNECTED_C) Blynk.virtualWrite(V2, dsTemp);

  // 2. SHT45 (V3 & V4)
  if (shtFound) {
    sensors_event_t humidity, temp;
    sht4.getEvent(&humidity, &temp);
    Blynk.virtualWrite(V3, temp.temperature);
    Blynk.virtualWrite(V4, humidity.relative_humidity);
  }

  // 3. Fluid Level (V5)
  digitalWrite(TRIG_PIN, LOW);
  delayMicroseconds(2);
```

```
  digitalWrite(TRIG_PIN, HIGH);
  delayMicroseconds(10);
  digitalWrite(TRIG_PIN, LOW);

  long duration = pulseIn(ECHO_PIN, HIGH);
  int distance = duration * 0.034 / 2; // Distance in cm

  // Calculate Percentage
  int levelPer = map(distance, TANK_HEIGHT, FULL_LEVEL, 0, 100);
  levelPer = constrain(levelPer, 0, 100);

  Blynk.virtualWrite(V5, levelPer);
  Serial.printf("Level: %d%% (%d cm)\n", levelPer, distance);
}

void setup() {
  Serial.begin(115200);
  pinMode(TRIG_PIN, OUTPUT);
  pinMode(ECHO_PIN, INPUT);

  Wire.begin();
  if (sht4.begin()) {
    sht4.setPrecision(SHT4X_HIGH_PRECISION);
    shtFound = true;
  }

  sensors.begin();
  simSerial.begin(115200, SERIAL_8N1, RXD2, TXD2);
  delay(5000);

  Blynk.begin(BLYNK_AUTH_TOKEN, modem, apn, "", "", "blynk.cloud", 80);
  timer.setInterval(15000L, sendAllData);
}

void loop() {
  Blynk.run();
  timer.run();
}
```

Use code with caution.

Fluid Level Calibration

- `TANK_HEIGHT`: Measure the distance from your sensor to the bottom of the empty tank.
- `FULL_LEVEL`: Measure the distance from your sensor to the water when the tank is full (leave a small gap).

Do you want to add an automatic relay to turn a pump ON/OFF based on these levels?

it is a float switch with 3 wires black, blue, brown

2 hours ago

A **3-wire float switch** (Black, Blue, Brown) typically acts as a SPDT (Single Pole Double Throw) switch, allowing you to detect both "Full" and "Empty" states. For your ESP32, you

An ESP32 bo
ultrasonic se
YouTub

Water leve
System usi
The Blynk IoT
used to moni
YouTub

will only use **two** of these wires. LinkedIn +2

1. Wiring for Tank Filling (Most Common)

To detect when the tank is **empty** and needs filling:

- **Black Wire (Common)**: Connect to **GND** on the ESP32.
- **Blue Wire (Normally Closed/NC when hanging)**: Connect to **GPIO 13** on the ESP32.
- **Brown Wire**: Not used; **must be insulated** (capped) for safety. Facebook +5

*Note: In this configuration, when the float hangs down (tank empty), the circuit is **closed**. When it floats up (tank full), the circuit **opens**.* ATO.com +2

2. Updated Code with Float Switch

This code adds a new **Blynk Datastream (V6)** for the float switch status.

cpp

```cpp
// ... [Keep your previous defines and libraries] ...

#define FLOAT_SWITCH_PIN 13 // Digital Input for Float Switch

void sendAllData() {
  // ... [Keep your DS18B20, SHT45, and Ultrasonic logic] ...

  // 4. Float Switch Status (V6)
  // Using INPUT_PULLUP: HIGH = Switch Open (Full), LOW = Switch Closed (l
  int floatStatus = digitalRead(FLOAT_SWITCH_PIN);

  if (floatStatus == LOW) {
    Blynk.virtualWrite(V6, "Tank Empty - Filling");
    Serial.println("Float Switch: Tank Empty");
  } else {
    Blynk.virtualWrite(V6, "Tank Full");
    Serial.println("Float Switch: Tank Full");
  }
}

void setup() {
  // ... [Keep your other setup code] ...

  // Initialize Float Switch with Internal Pullup
  pinMode(FLOAT_SWITCH_PIN, INPUT_PULLUP);

  // ... [Keep your Blynk.begin and timers] ...
}

void loop() {
  Blynk.run();
  timer.run();
}
```

Use code with caution.

3. Dashboard Setup

- **V6**: Name: `Tank Status`, Type: `String`.
- **Widget**: Use a **Value Display** linked to **V6** to show the text status.

Automatin
Tanks Usin
Float Switch
behave very
LinkedIn

Konvio Nee

Safety & Reliability Tips

- **Internal Pull-up**: Using `INPUT_PULLUP` simplifies wiring as you don't need an external resistor.
- **Voltage**: Float switches are often rated for high AC voltage, but for the ESP32, you are only using them as a **low-voltage signal switch**.
- **Distance**: If the float switch is far from the ESP32, consider using a **10kΩ external pull-up resistor** for a stronger signal and better noise immunity. Zbotic +2

Would you like to add a **Blynk Button** to manually override and turn on a pump regardless of the float switch?

give the whole code

2 hours ago

This is the complete, integrated code for your **ESP32** and **A7670C** 4G module. It manages the **Airtel M2M** connection, **DS18B20** (V2), **SHT45** (V3/V4), and the **Float Switch** (V6).

1. Final Wiring Summary

Component	ESP32 Pin	Connection Note
A7670C TX	**GPIO 16**	Data to ESP32
A7670C RX	**GPIO 17**	Data from ESP32
DS18B20	**GPIO 4**	**Requires 4.7k resistor** to 3.3V
SHT45 SDA	**GPIO 21**	I2C Data
SHT45 SCL	**GPIO 22**	I2C Clock
Float Switch	**GPIO 13**	**Black** to GND, **Blue** to Pin 13

2. Complete Integrated Code

cpp

```cpp
#define BLYNK_TEMPLATE_ID "TMPL3z0OuMdNy"

  // 6. Set Timer (Every 15 seconds)
  timer.setInterval(15000L, sendAllData);
}

void loop() {
  Blynk.run();
  timer.run();
}
```

Use code with caution.

3. Final Dashboard Checklist

- **V2**: Datastream "DS18B20 Temp" (Double/Float).
- **V3**: Datastream "SHT45 Temp" (Double/Float).
- **V4**: Datastream "SHT45 Humidity" (Double/Float).
- **V6**: Datastream "Fluid Status" (**String**).

Would you like me to add code for a Relay on V7 to automatically turn a pump ON when the float switch hits LOW?

now I need to add the nextion display to the code too

To add a **Nextion HMI display** to your current project, you will use the ESP32's **Serial1** port. This keeps your **Serial2** free for the A7670C and your main **Serial** free for debugging. YouTube +3

1. Wiring Connections

The Nextion display needs a **stable 5V** source. Do not power it directly from the ESP32's 5V pin, as it can draw enough current to cause "brownouts" (resets). Zbotic +1

Nextion Pin	ESP32 Pin	Notes
VCC	**External 5V/2A**	Do not use ESP32 5V pin
GND	**GND**	Share common ground with ESP32
TX	**GPIO 32 (RX1)**	Connect Nextion TX to ESP32 RX

RX	**GPIO 33 (TX1)**	Connect Nextion RX to ESP32 TX

2. Nextion Editor Setup

In your Nextion project, create **Text** or **Number** objects with these names (Object Names):

- `t0` — To show DS18B20 Temp
- `t1` — To show SHT45 Temp
- `t2` — To show SHT45 Humidity
- `t3` — To show Fluid Level Status

3. Integrated Code with Nextion Support

This code sends data to both **Blynk** and the **Nextion Display** simultaneously.

cpp

```cpp
#define BLYNK_TEMPLATE_ID "TMPL3z0OuMdNy"

    sht4.getEvent(&humidity, &temp);
    Blynk.virtualWrite(V3, temp.temperature);
    Blynk.virtualWrite(V4, humidity.relative_humidity);
    sendToNextion("t1", String(temp.temperature, 1) + " C");
    sendToNextion("t2", String(humidity.relative_humidity, 0) + " %");
  }

  // 3. Float Switch (V6 & Nextion t3)
  int status = digitalRead(FLOAT_SWITCH);
  String tankMsg = (status == LOW) ? "EMPTY" : "FULL";
  Blynk.virtualWrite(V6, tankMsg);
  sendToNextion("t3", tankMsg);
}

void setup() {

  Serial.begin(115200);

  // Nextion Serial Initialized at default 9600
  nexSerial.begin(9600, SERIAL_8N1, RXD1, TXD1);

  pinMode(FLOAT_SWITCH, INPUT_PULLUP);
  Wire.begin();
  if (sht4.begin()) shtFound = true;
  sensors.begin();

  simSerial.begin(115200, SERIAL_8N1, RXD2, TXD2);
  delay(5000);

  Blynk.begin(BLYNK_AUTH_TOKEN, modem, apn, "", "", "blynk.cloud", 80);
  timer.setInterval(15000L, sendAllData);
}

void loop() {
  Blynk.run();
  timer.run();
}
```

Use code with caution.

Pro-Tips for Nextion

- **End Characters**: Every command sent to Nextion must end with three `0xFF` bytes.
- **Baud Rate**: If the Nextion doesn't show anything, try changing `nexSerial.begin(9600)` to `nexSerial.begin(115200)` if you previously changed the display's internal baud rate.
- **Object Names**: The `sendToNextion` function expects the object on your screen to be a **Text** box. If you used a **Number** box, change `.txt=` to `.val=` in the function code. YouTube +1

Do you have the Nextion HMI file (.tft) already designed, or do you need help with the Nextion Editor setup?

I need an average of both the temprature readings and it needs to be shown on the x0, x2 must show the humidity, b9 ..

To update your **Nextion Display** and **Blynk** with these specific logic changes, we will calculate the average of the DS18B20 and SHT45, and then use Nextion's `pic` attribute (for button/image `b9`) to show the tank status visually.

1. Nextion Component Requirements

In your Nextion Editor, ensure you have:

- **x0**: A "Number" or "Float" variable for **Average Temp**.
- **x2**: A "Number" or "Float" variable for **Humidity**.
- **b9**: A "Button" or "Variable" that changes its **pic** or **txt** attribute based on the tank.

2. Integrated Final Code

cpp

```cpp
#define BLYNK_TEMPLATE_ID "TMPL3z0OuMdNy"

  timer.setInterval(10000L, sendAllData);
}

void loop() {
  Blynk.run();
  timer.run();
```

```
}
```

Use code with caution.

Important Nextion Notes:

1. **Float Components (`x0` , `x2`)**: These usually store values as integers in the Nextion memory. To show `25.5` , the code sends `255` and the Nextion component's `vvs1` attribute should be set to `1` (for 1 decimal point).
2. **Button `b9`** : I used `.txt` to change the label. If you want the **color** to change, use `b9.bco=63488` (Red for empty) or `b9.bco=2016` (Green for full).
3. **Timing**: The data refreshes every **10 seconds**.

Does the **Nextion** show the values now, or do we need to adjust the **baud rate** for the display?

the esp also need to have 7 relay connected to it where if no current provided then the device connected to relay must ...

To achieve this, you need to **use Normally Closed (NC) wiring on your relays**. In this setup, the circuit is complete (device ON) by default when the ESP32 is off or the relay is not energized. When you "send current" (set the ESP32 pin to `HIGH`), the relay clicks and breaks the circuit (device OFF).

1. Wiring for "Default ON"

Most relay modules have three terminals: **COM** (Common), **NO** (Normally Open), and **NC** (Normally Closed).

- **Device Wire 1:** Connect to **COM**.
- **Device Wire 2:** Connect to **NC**.
- *Result:* The device runs even if the ESP32 is disconnected. Setting the ESP32 pin to `HIGH` stops the device.

2. ESP32 Relay Pin Map

Since you are already using many pins for GSM, Nextion, and Sensors, here are the safest 7 pins left for your relays:

- **Relays:** GPIO 2, 12, 14, 15, 25, 26, 27.

3. Updated Code with 7 Relays

This code adds **7 Blynk Buttons (V10 to V16)** to control the relays.

cpp

```cpp
// ... [Keep all previous defines and libraries] ...

// 7 Relay Pins
int relayPins[7] = {2, 12, 14, 15, 25, 26, 27};

// Blynk Control for Relays (V10 to V16)
BLYNK_WRITE(V10) { digitalWrite(relayPins[0], param.asInt()); }
```

```
BLYNK_WRITE(V11) { digitalWrite(relayPins[1], param.asInt()); }
BLYNK_WRITE(V12) { digitalWrite(relayPins[2], param.asInt()); }
BLYNK_WRITE(V13) { digitalWrite(relayPins[3], param.asInt()); }
BLYNK_WRITE(V14) { digitalWrite(relayPins[4], param.asInt()); }
BLYNK_WRITE(V15) { digitalWrite(relayPins[5], param.asInt()); }
BLYNK_WRITE(V16) { digitalWrite(relayPins[6], param.asInt()); }

void setup() {
  // ... [Keep existing Serial, Sensors, and GSM setup] ...

  // Initialize Relays
  for (int i = 0; i < 7; i++) {
    pinMode(relayPins[i], OUTPUT);
    digitalWrite(relayPins[i], LOW); // LOW = Device ON (NC Wiring)
  }

  Blynk.begin(BLYNK_AUTH_TOKEN, modem, apn, "", "", "blynk.cloud", 80);
  timer.setInterval(10000L, sendAllData);
}

void loop() {
  Blynk.run();
  timer.run();
}
```

Use code with caution.

4. Blynk App Setup

1. Add 7 **Button Widgets**.
2. Set them to **V10, V11, V12, V13, V14, V15, and V16**.
3. Set Mode to **Switch**.
4. **Logic:**
   - Button **OFF** (0) → ESP32 Pin **LOW** → Relay NC remains closed → **Device ON**.
   - Button **ON** (1) → ESP32 Pin **HIGH** → Relay clicks open → **Device OFF**.

Important Power Warning

Do **not** power 7 relays directly from the ESP32's 5V/VIN pin. Relays draw significant current. Use a separate **5V 2A power supply** for the relay board's `VCC/JD-VCC` and connect the **GND** of that supply to the ESP32 **GND**.

Should I add the relay status to your Nextion display as well?

I need the relays to be able to operate manually and by code logic Both according to the conditions which would be ...

To make this work, we use **Dual Logic**: The relays will trigger automatically based on sensor thresholds (like temperature or tank level), but you can "Force Stop" or "Force Start" them using **Blynk Buttons**.

1. The Logic Plan

- **Automatic Mode:** If Temperature > 30°C or Tank is Empty, the Relay turns **ON**.

- **Manual Override:** If you press the Blynk Button, it overrides the sensor for that specific relay.
- **NC Wiring Reminder:** Since you are using **Normally Closed (NC)**, `digitalWrite(pin, LOW)` keeps the device **ON**.

2. Updated Integrated Code

This code includes the 7 Relays, Logic for Temp/Tank, and Blynk Overrides.

cpp

```cpp
#define BLYNK_TEMPLATE_ID "TMPL3z0OuMdNy"
#define BLYNK_TEMPLATE_NAME "try01"
#define BLYNK_AUTH_TOKEN "Wf5Ze5ZhyWuGEa_qNFpVUaLR4v_r_Acj"

#define TINY_GSM_MODEM_SIM7600
#define BLYNK_PRINT Serial

#include <Wire.h>
#include <Adafruit_SHT4x.h>
#include <OneWire.h>
#include <DallasTemperature.h>

#include <TinyGsmClient.h>
#include <BlynkSimpleTinyGSM.h>

// Pins
#define SENSOR_PIN 4
#define FLOAT_SWITCH 13
#define RXD2 17         // GSM RX
#define TXD2 16         // GSM TX
#define RXD1 32         // Nextion RX
#define TXD1 33         // Nextion TX

// 7 Relay Pins
int relayPins[] = {2, 12, 14, 15, 25, 26, 27};
bool manualOverride[] = {false, false, false, false, false, false, false};
int relayState[] = {LOW, LOW, LOW, LOW, LOW, LOW, LOW}; // LOW = ON (NC)

const char apn[] = "airteliot.com";

HardwareSerial simSerial(2);
HardwareSerial nexSerial(1);
TinyGsm modem(simSerial);
OneWire oneWire(SENSOR_PIN);
DallasTemperature sensors(&oneWire);
Adafruit_SHT4x sht4 = Adafruit_SHT4x();
BlynkTimer timer;

bool shtFound = false;

// Blynk Manual Controls (V10 - V16)
BLYNK_WRITE(V10) { manualOverride[0] = param.asInt(); digitalWrite(relayP
BLYNK_WRITE(V11) { manualOverride[1] = param.asInt(); digitalWrite(relayP
// ... (Repeat for V12-V16 if needed)

void sendAllData() {
  sensors.requestTemperatures();
  float dsTemp = sensors.getTempCByIndex(0);

  sensors_event_t humidity, temp;
  float shtTemp = 0, shtHum = 0;
  if (shtFound) {
    sht4.getEvent(&humidity, &temp);
```

```
    shtTemp = temp.temperature;
    shtHum = humidity.relative_humidity;
  }

  float avgTemp = (dsTemp + shtTemp) / 2.0;
  int tankStatus = digitalRead(FLOAT_SWITCH);

  // --- AUTOMATIC LOGIC ---

  // Relay 0 Logic: If Avg Temp > 35, Turn OFF (HIGH), else ON (LOW)
  if (!manualOverride[0]) {
    if (avgTemp > 35.0) relayState[0] = HIGH;
    else relayState[0] = LOW;
    digitalWrite(relayPins[0], relayState[0]);
  }

  // Relay 1 Logic: If Tank is EMPTY (LOW), Turn ON (LOW)
  if (!manualOverride[1]) {
    if (tankStatus == LOW) relayState[1] = LOW;
    else relayState[1] = HIGH;
    digitalWrite(relayPins[1], relayState[1]);
  }

  // --- SEND TO NEXTION & BLYNK ---
  nexSerial.print("x0.val=" + String((int)(avgTemp * 10))); nexSerial.wri
  nexSerial.print("x2.val=" + String((int)(shtHum * 10))); nexSerial.write

  if (tankStatus == LOW) {
    nexSerial.print("b9.txt=\"EMPTY\"");
  } else {
    nexSerial.print("b9.txt=\"FILLED\"");
  }
  nexSerial.write(0xff); nexSerial.write(0xff); nexSerial.write(0xff);

  Blynk.virtualWrite(V2, avgTemp);
  Blynk.virtualWrite(V4, shtHum);
}

void setup() {
  Serial.begin(115200);
  nexSerial.begin(9600, SERIAL_8N1, RXD1, TXD1);

  for (int i=0; i<7; i++) {
    pinMode(relayPins[i], OUTPUT);
    digitalWrite(relayPins[i], LOW); // All devices ON by default
  }

  pinMode(FLOAT_SWITCH, INPUT_PULLUP);
  Wire.begin();
  if (sht4.begin()) shtFound = true;
  sensors.begin();

  simSerial.begin(115200, SERIAL_8N1, RXD2, TXD2);
  delay(5000);

  Blynk.begin(BLYNK_AUTH_TOKEN, modem, apn, "", "", "blynk.cloud", 80);
  timer.setInterval(10000L, sendAllData);
}

void loop() {
  Blynk.run();
  timer.run();
}
```

Use code with caution.

3. How to use this:

1. **Manual Overide:** In the Blynk app, if you turn the switch **ON** (V10), the ESP32 pin goes **HIGH**, and the relay breaks the circuit (**Device OFF**).
2. **Auto Logic:** If you leave the Blynk switch **OFF**, the code checks if the `avgTemp > 35`. If it is, it kills the power to Relay 0.
3. **Tank Logic:** Relay 1 will automatically turn **ON** (LOW) if the float switch drops to **EMPTY**.

Which specific conditions (Temperature or Humidity values) do you want for the other 5 relays?

one of the relay is for work light in the machine another for primary heater ...

To implement this logic, we will map each relay to a specific function and assign the automated conditions. Since you are using **NC (Normally Closed)** wiring, **LOW = Device ON** and **HIGH = Device OFF**.

1. Relay Function Mapping

Relay	ESP32 Pin	Function	Logic / Condition
R0	**GPIO 2**	Work Light	Manual Only (Blynk V10)
R1	**GPIO 12**	Primary Heater	ON if `avgTemp` < 35°C
R2	**GPIO 14**	Secondary Heater	ON if `avgTemp` < 30°C (Boost)
R3	**GPIO 15**	Tilt UP	ON if Tank is EMPTY
R4	**GPIO 25**	Tilt DOWN	ON if Tank is FULL
R5	**GPIO 26**	Primary Fan	ON if `avgTemp` > 40°C
R6	**GPIO 27**	Secondary Fan	ON if Humidity > 70%

2. Complete Integrated Code

cpp

```cpp
#define BLYNK_TEMPLATE_ID "TMPL3z0OuMdNy"
#define BLYNK_TEMPLATE_NAME "try01"

#define BLYNK_AUTH_TOKEN "Wf5Ze5ZhyWuGEa_qNFpVUaLR4v_r_Acj"

#define TINY_GSM_MODEM_SIM7600
#define BLYNK_PRINT Serial

#include <Wire.h>
#include <Adafruit_SHT4x.h>
#include <OneWire.h>
#include <DallasTemperature.h>
```

```
#include <TinyGsmClient.h>
#include <BlynkSimpleTinyGSM.h>

// Pins
#define SENSOR_PIN 4
#define FLOAT_SWITCH 13
#define RXD2 17         // GSM RX
#define TXD2 16         // GSM TX
#define RXD1 32         // Nextion RX
#define TXD1 33         // Nextion TX

// Relay Mapping
const int R_LIGHT = 2, R_HEAT1 = 12, R_HEAT2 = 14, R_TILT_UP = 15, R_TILT_

BLYNK_WRITE(V16) { manualMode[6] = true; digitalWrite(R_FAN2, param.asInt

void updateRelays(float temp, float hum, int tank) {
  // Logic for Auto Mode (If manual override is NOT active)
  if (!manualMode[1]) digitalWrite(R_HEAT1, (temp < 35.0) ? LOW : HIGH);
  if (!manualMode[2]) digitalWrite(R_HEAT2, (temp < 30.0) ? LOW : HIGH);
  if (!manualMode[3]) digitalWrite(R_TILT_UP, (tank == LOW) ? LOW : HIGH);
  if (!manualMode[4]) digitalWrite(R_TILT_DN, (tank == HIGH) ? LOW : HIGH
  if (!manualMode[5]) digitalWrite(R_FAN1, (temp > 40.0) ? LOW : HIGH);
  if (!manualMode[6]) digitalWrite(R_FAN2, (hum > 70.0) ? LOW : HIGH);
}

void sendAllData() {
  sensors.requestTemperatures();
  float dsTemp = sensors.getTempCByIndex(0);
  sensors_event_t humidity, s_temp;
  float shtTemp = 0, shtHum = 0;
  if (shtFound) { sht4.getEvent(&humidity, &s_temp); shtTemp = s_temp.temp

  float avgTemp = (dsTemp + shtTemp) / 2.0;
  int tankStatus = digitalRead(FLOAT_SWITCH);

  updateRelays(avgTemp, shtHum, tankStatus);

  // Nextion Updates
  nexSerial.print("x0.val=" + String((int)(avgTemp * 10))); nexSerial.wri
  nexSerial.print("x2.val=" + String((int)(shtHum * 10))); nexSerial.write
  nexSerial.print("b9.txt=\"" + String((tankStatus == LOW) ? "EMPTY" : "F

  Blynk.virtualWrite(V2, avgTemp);
  Blynk.virtualWrite(V4, shtHum);
  Blynk.virtualWrite(V6, (tankStatus == LOW) ? "Empty" : "Full");
}
```

```
void setup() {
  Serial.begin(115200);
  nexSerial.begin(9600, SERIAL_8N1, RXD1, TXD1);
  for (int i=0; i<7; i++) { pinMode(relayPins[i], OUTPUT); digitalWrite(re
  pinMode(FLOAT_SWITCH, INPUT_PULLUP);
  Wire.begin();

  if (sht4.begin()) shtFound = true;
  sensors.begin();
  simSerial.begin(115200, SERIAL_8N1, RXD2, TXD2);
  delay(5000);
  Blynk.begin(BLYNK_AUTH_TOKEN, modem, apn, "", "", "blynk.cloud", 80);
  timer.setInterval(10000L, sendAllData);
}

void loop() { Blynk.run(); timer.run(); }
```

Use code with caution.

3. Usage Tip:

To return a relay to **Auto Mode** after a manual override, you would need to reset the `manualMode` flag (e.g., via another button). For now, once you press a button in Blynk, that relay stays in the state you chose until the ESP32 restarts.

Should I add a **"Reset to Auto"** button on **V17** to clear all manual overrides?

now let me tell you the logic and conditions
the secondary heater only starts when the primary is on ...

To implement this complex interconnected logic, we need to use **Blynk Sync** and **Nextion bi-directional communication**.

1. The Strategy

- **Syncing:** We use `BLYNK_WRITE` for dashboard inputs and `nexSerial.available()` for Nextion inputs.
- **Relay Logic:**
  - **Secondary Heater:** Controlled by `Primary_Heater_Status && Condition`.
  - **Secondary Fan (2-Speed):** Since a standard relay can't change motor speed, you must wire the fan's "Low Speed" wire to a permanent power source and the "High Speed" wire to **Relay 6**. When the relay triggers, it overrides the low speed.
  - **Thresholds:** I have added variables for `tempThreshold` and `humThreshold` so you can adjust them.

2. Full Integrated Code

cpp

```
#define BLYNK_TEMPLATE_ID "TMPL3z0OuMdNy"
#define BLYNK_TEMPLATE_NAME "try01"
#define BLYNK_AUTH_TOKEN "Wf5Ze5ZhyWuGEa_qNFpVUaLR4v_r_Acj"
```

```
#define TINY_GSM_MODEM_SIM7600
#define BLYNK_PRINT Serial

#include <Wire.h>
#include <Adafruit_SHT4x.h>
#include <OneWire.h>

      // 3. Secondary Heater Logic (Only if Primary is ON)
      if (avgTemp < (tempThreshold - 5.0)) {
        digitalWrite(R_HEAT2, LOW); // Heater 2 ON (Boost)
      } else {
        digitalWrite(R_HEAT2, HIGH);
      }
    } else {
      digitalWrite(R_HEAT1, HIGH);
      digitalWrite(R_HEAT2, HIGH);
    }
  }

  // 4. Tilt Logic
  digitalWrite(R_TILT_UP, (tank == LOW) ? LOW : HIGH);
  digitalWrite(R_TILT_DN, (tank == HIGH) ? LOW : HIGH);
}

void sendAllData() {
  sensors.requestTemperatures();
  float dsTemp = sensors.getTempCByIndex(0);
  sensors_event_t humidity, s_temp;
  float shtTemp = 0, shtHum = 0;
  if (shtFound) { sht4.getEvent(&humidity, &s_temp); shtTemp = s_temp.temp

  float avgTemp = (dsTemp + shtTemp) / 2.0;
  int tankStatus = digitalRead(FLOAT_SWITCH);

  processLogic(avgTemp, shtHum, tankStatus);

  // Sync to Nextion
  nexSerial.print("x0.val=" + String((int)(avgTemp * 10))); nexSerial.writ
  nexSerial.print("x2.val=" + String((int)(shtHum * 10))); nexSerial.write

  // Sync to Blynk
  Blynk.virtualWrite(V2, avgTemp);
  Blynk.virtualWrite(V4, shtHum);
  Blynk.virtualWrite(V6, (tankStatus == LOW) ? "Empty" : "Full");
}

void setup() {
  Serial.begin(115200);

  nexSerial.begin(9600, SERIAL_8N1, RXD1, TXD1);

  for (int i=0; i<7; i++) {
    pinMode(relayPins[i], OUTPUT);
    digitalWrite(relayPins[i], HIGH); // Start all OFF (HIGH) for safety
  }

  pinMode(FLOAT_SWITCH, INPUT_PULLUP);
  Wire.begin();
  if (sht4.begin()) shtFound = true;
  sensors.begin();

  simSerial.begin(115200, SERIAL_8N1, RXD2, TXD2);
  delay(5000);
  Blynk.begin(BLYNK_AUTH_TOKEN, modem, apn, "", "", "blynk.cloud", 80);

  timer.setInterval(10000L, sendAllData);
}

void loop() {
  Blynk.run();
  timer.run();

  // Listen for Nextion Button Presses (Interconnection)
  if (nexSerial.available()) {
    String data = nexSerial.readStringUntil('\n');
```

```
    String data = nexSerial.readStringUntil('\n');
    if (data.indexOf("LIGHT_ON") > -1) {
      digitalWrite(R_LIGHT, LOW);
      Blynk.virtualWrite(V10, 1);
    }
    if (data.indexOf("LIGHT_OFF") > -1) {
      digitalWrite(R_LIGHT, HIGH);
      Blynk.virtualWrite(V10, 0);
    }
  }
}
```

Use code with caution.

3. Interconnection Setup

1. **Nextion to Blynk:** In your Nextion Editor, for the Light Button, add a "Touch Release Event" that sends `print "LIGHT_ON\n"`. The ESP32 `loop()` will catch this and update the Blynk App.
2. **Blynk to Nextion:** When you toggle the button on your phone, the `BLYNK_WRITE(V10)` function sends the update to the Nextion display automatically.

4. Secondary Fan Wiring

Since you need the fan to run on **Low** by default and **High** on command:

- Connect the **Low Speed wire** of the fan directly to the power source.
- Connect the **High Speed wire** through **Relay 6 (NC)**. When Relay 6 is triggered (LOW), the high-speed winding will take over.

Do you have the exact Temperature and Humidity threshold values you want to use?

we should be able to set the threshold too on the display and dashboard

To allow you to set thresholds from both the **Nextion Display** and the **Blynk Dashboard**, we use **Virtual Pins (V20, V21)** and **Nextion Variables**.

When you change the value on your phone, it updates the ESP32 and the Display. When you change it on the Display, it updates the ESP32 and the Phone.

1. Dashboard & Display Setup

- **Blynk:** Add two **Step Widgets** or **Sliders**.
  - **V20**: Temp Threshold (Range 0-100)
  - **V21**: Humidity Threshold (Range 0-100)
- **Nextion:** Add two **Number (n0, n1)** or **Float (x1, x3)** components.
  - **n0**: Temp Threshold
  - **n1**: Hum Threshold
  - In the Nextion "Touch Release Event" for these numbers, add: `printh 23 02 54 00` (This sends a custom serial trigger to the ESP32).

2. Updated Integrated Code

cpp

```cpp
#define BLYNK_TEMPLATE_ID "TMPL3z0OuMdNy"

void loop() {
  Blynk.run();
  timer.run();

  // --- NEXTION SYNC (Display to ESP & Blynk) ---
  if (nexSerial.available()) {
    // Example: Nextion sends "T30" to set temp threshold to 30
```

```
    String nexData = nexSerial.readStringUntil('\n');
    if (nexData.startsWith("T")) {
      tempThreshold = nexData.substring(1).toFloat();
      Blynk.virtualWrite(V20, tempThreshold);
    }
    if (nexData.startsWith("H")) {
      humThreshold = nexData.substring(1).toFloat();
      Blynk.virtualWrite(V21, humThreshold);
    }
  }
}
```

Use code with caution.

3. How to Sync from Nextion

In the Nextion Editor, for the "Save" button after changing a number:

1. Go to the **Touch Release Event**.
2. Add: `printf "T%d\n",n0.val` (Assuming **n0** is your Temp Threshold).
3. Add: `printf "H%d\n",n1.val` (Assuming **n1** is your Hum Threshold).

This sends the data over Serial, the ESP32 updates its local variable, and then sends the update to your phone via `Blynk.virtualWrite`.

Do you have the Nextion components named n0 and n1, or should we use different names?

can you give all the connections we made

Based on our complete setup, here is the master wiring guide for your **ESP32**, **A7670C 4G Module**, **Nextion HMI**, **Sensors**, and **Relays**.

1. Power Supply (Critical)

- **External 5V/3A Power Source:** Connect to the **VCC** of the A7670C, the **Relay Board**, and the **Nextion Display**.
- **Common Ground:** Connect the **GND** of the External Power Supply, ESP32, A7670C, Nextion, and all sensors together.

---

2. Communication & Display

Component	ESP32 Pin	Logic	Notes
A7670C TX	**GPIO 16 (RX2)**	3.3V/1.8V	Receives data from 4G module
A7670C RX	**GPIO 17 (TX2)**	3.3V/1.8V	Sends commands to 4G module
Nextion TX	**GPIO 32 (RX1)**	3.3V	Receives data from HMI
Nextion RX	**GPIO 33 (TX1)**	3.3V	Sends data to HMI

---

3. Sensors

Sensor	ESP32 Pin	Connection	Notes
DS18B20 (Data)	**GPIO 4**	OneWire	**Must have 4.7kΩ resistor** to 3.3V
SHT45 (SDA)	**GPIO 21**	I2C	Data line
SHT45 (SCL)	**GPIO 22**	I2C	Clock line
Float Switch	**GPIO 13**	Digital	**Black** to GND, **Blue** to Pin 13

---

4. 7-Channel Relays (Normally Closed - NC)

- **Wiring:** Connect the device "Live" wire to **COM** and **NC**.
- **Operation: LOW** = Device ON (Default), **HIGH** = Device OFF (Commanded).

Relay	ESP32 Pin	Function
Relay 0	**GPIO 2**	Work Light
Relay 1	**GPIO 12**	Primary Heater
Relay 2	**GPIO 14**	Secondary Heater (Boost)
Relay 3	**GPIO 15**	Tilt UP
Relay 4	**GPIO 25**	Tilt DOWN
Relay 5	**GPIO 26**	Primary Fan
Relay 6	**GPIO 27**	Secondary Fan (High Speed)

---

5. Nextion Components Checklist

Ensure your `.HMI` file uses these exact object names for the code to sync:

- **x0**: Average Temperature (vvs1=1)
- **x2**: Humidity (vvs1=1)
- **n0**: Temperature Threshold (Set via `T%d\n`)
- **n1**: Humidity Threshold (Set via `H%d\n`)
- **b9**: Tank Status Text ("EMPTY" / "FILLED")
- **bt0**: Work Light Status Toggle

Would you like a **schematic diagram description** for how to wire the **Secondary Fan** for its two speeds?

the x1 and x3 are for setting up the temprature and humidity threshold on nextion display and we need that on the ...

To sync **x1** (Temperature Threshold) and **x3** (Humidity Threshold) between your **Nextion**

To sync **x1** (Temperature Threshold) and **x3** (Humidity Threshold) between your **Nextion Display**, **ESP32**, and **Blynk Dashboard**, we use a two-way synchronization logic.

In Nextion, "x" components (floats) handle decimals by multiplying the value by 10 (e.g., 35.5 is stored as 355). The code below accounts for this scaling.

1. Blynk Dashboard Setup

- **V20**: Slider or Step Widget (Range 0–100, Step 0.1) for **Temp Threshold**.
- **V21**: Slider or Step Widget (Range 0–100, Step 0.1) for **Hum Threshold**.

2. Nextion Component Settings

- **x1**: `vvs1` set to `1` (1 decimal place).
- **x3**: `vvs1` set to `1` (1 decimal place).
- **Event**: In the "Touch Release Event" for these components, add:
  `printf "T%d\n",x1.val`
  `printf "H%d\n",x3.val`

3. Final Integrated Code

cpp

```cpp
#define BLYNK_TEMPLATE_ID "TMPL3z0OuMdNy"

  if (nexSerial.available()) {
    String nexData = nexSerial.readStringUntil('\n');
    if (nexData.startsWith("T")) {
      tempThreshold = nexData.substring(1).toFloat() / 10.0;
      Blynk.virtualWrite(V20, tempThreshold);
    }
    if (nexData.startsWith("H")) {
      humThreshold = nexData.substring(1).toFloat() / 10.0;
      Blynk.virtualWrite(V21, humThreshold);
    }
  }
}
```

Use code with caution.

Summary of Changes:

1. **Scaling**: Added `/ 10.0` when reading from Nextion and `* 10` when sending to Nextion to correctly handle decimal points.
2. **Mapping**: Changed `n0/n1` to `x1/x3` to match your specific HMI design.
3. **Synchronization**: Every time you change a threshold on the display, the **Blynk Slider** on your phone will move automatically, and vice versa.

Do you have the **Nextion Baud rate** confirmed at 9600, or should we increase it for faster response?

can you name all the data streams that need to be created on the dashboard and its parameters too and what to do in the ...

To achieve full synchronization between your **Blynk Dashboard**, **Nextion Display**, and **ESP32**, you must create matching Datastreams and HMI components.

1. Blynk Datastream Requirements

Create these **Virtual Pin** datastreams in your Blynk Console (Templates > Datastreams).

Function	Pin	Data Type	Min / Max	Unit	Widget Suggestion
Avg. Temperature	**V2**	Double	-40 to 125	°C	Gauge / Chart
Humidity	**V4**	Double	0 to 100	%	Gauge / Chart
Tank Status	**V6**	String	N/A	N/A	Value Display
Work Light	**V10**	Integer	0 to 1	N/A	Switch / Button
Temp Threshold	**V20**	Double	0 to 100	°C	Slider / Step
Hum Threshold	**V21**	Double	0 to 100	%	Slider / Step

*Note: For V11–V16 (other relays), use **Integer** type with 0–1 range.* Blynk +2

---

2. Nextion Display Configuration

In the **Nextion Editor**, set up these components with the exact names used in the code.

- **Current Readings**:
  - **x0**: Average Temp. Set `vvs1` to `1` (displays 1 decimal place).
  - **x2**: Humidity. Set `vvs1` to `1`.
- **Threshold Settings (Bi-directional)**:
  - **x1**: Temp Threshold. Set `vvs1` to `1`.
  - **x3**: Hum Threshold. Set `vvs1` to `1`.
  - **Important**: In the **Touch Release Event** for x1 and x3, add this code:
    `printf "T%d\n",x1.val` (for temp)
    `printf "H%d\n",x3.val` (for humidity)
- **Status & Control**:
  - **b9**: A Text field for "EMPTY" or "FILLED".
  - **bt0**: A Dual-state button for the Work Light. Arduino Forum +2

---

3. What to do in the ESP32 Code

The code must act as a bridge to ensure when one interface changes, the other follows instantly.

- **From Blynk to Nextion**:
  Inside each `BLYNK_WRITE(V_PIN)` function, add a line to send the new value to the Nextion Serial port (e.g., `nexSerial.print("x1.val=...");`).
- **From Nextion to Blynk**:
  In your `loop()`, use `nexSerial.readStringUntil('\n')` to listen for the "T" or "H" prefixes sent by the display. When received, update the threshold variable and call `Blynk.virtualWrite(V_PIN, value)` to update your phone.
- **Scaling Logic**:
  Nextion "x" components are integers that represent floats (e.g., `25.5` is stored as `255`). Always **multiply by 10** when sending from ESP32 to Nextion, and **divide by 10** when receiving from Nextion to ESP32. Arduino Forum +5

Would you like me to generate the final, clean version of the loop() and sync functions for this bi-directional setup?

functions for this bi-directional setup?

the v0 and v1 are for the temprature readings v2 for humidity readings and v3 for water tank already

Understood. Let's re-map the **Blynk Datastreams** to match your existing setup (**V0, V1, V2, V3**) and integrate the **Nextion (x1, x3)** threshold synchronization.

1. Updated Blynk Datastream Map

Function	Pin	Type	Min/Max	Nextion
DS18B20 Temp	**V0**	Double	-40 to 125	(Internal)
SHT45 Temp	**V1**	Double	-40 to 125	(Internal)
Average Temp	**V0/V1 Avg**	(Logic)	N/A	**x0**
Humidity	**V2**	Double	0 to 100	**x2**
Tank Status	**V3**	String	N/A	**b9**
Work Light	**V10**	Integer	0 to 1	**bt0**
Temp Threshold	**V20**	Double	0 to 100	**x1**
Hum Threshold	**V21**	Double	0 to 100	**x3**

---

2. Full Integrated Code

      Blynk.virtualWrite(V20, tempThreshold);
    }
    if (nexData.startsWith("H")) {
      humThreshold = nexData.substring(1).toFloat() / 10.0;
      Blynk.virtualWrite(V21, humThreshold);
    }
  }
}
```

Use code with caution.

3. Nextion "Touch Release" Instructions

For the **x1** (Temp) and **x3** (Hum) threshold objects, go to the **Touch Release Event** tab in the Nextion Editor and enter:

- **For x1:** `printh 54` followed by `printf "T%d\n",x1.val`
- **For x3:** `printh 48` followed by `printf "H%d\n",x3.val`

This ensures that as soon as you change the value on the screen, the ESP32 receives it, updates the logic, and pushes the change to your **Blynk App**.

Does your SHT45 wiring use the default GPIO 21 and 22, or have you moved them to different pins?

I could be able to do the other way around too
as I change the threshold on the dashboard it must get it an...

To achieve full two-way synchronization, the ESP32 must update the Nextion display whenever a change is detected from the **Blynk Dashboard**.

I have updated the `BLYNK_WRITE` functions for **V20** and **V21** to send the new values to Nextion objects **x1** and **x3** immediately. I also added a `Blynk.syncVirtual(V20, V21)` call in the `setup()` so that the hardware retrieves your last saved thresholds from the cloud as soon as it boots up.

1. Updated Two-Way Sync Code

cpp

```cpp
// --- BLYNK to ESP & NEXTION (Two-Way Sync) ---

// When you move the Slider on Blynk App (V20):
BLYNK_WRITE(V20) {
  tempThreshold = param.asFloat();
  Serial.print("Blynk Temp Threshold Update: "); Serial.println(tempThresl

  // Update Nextion x1 immediately
  nexSerial.print("x1.val=" + String((int)(tempThreshold * 10)));
  nexSerial.write(0xff); nexSerial.write(0xff); nexSerial.write(0xff);
}

// When you move the Slider on Blynk App (V21):
BLYNK_WRITE(V21) {
  humThreshold = param.asFloat();
  Serial.print("Blynk Hum Threshold Update: "); Serial.println(humThresho

  // Update Nextion x3 immediately
  nexSerial.print("x3.val=" + String((int)(humThreshold * 10)));
  nexSerial.write(0xff); nexSerial.write(0xff); nexSerial.write(0xff);
}

// --- NEXTION to ESP & BLYNK (Two-Way Sync) ---
void checkNextionInput() {
  if (nexSerial.available()) {
    String nexData = nexSerial.readStringUntil('\n');

    // If Nextion sends "T355" (meaning 35.5)
    if (nexData.startsWith("T")) {
      tempThreshold = nexData.substring(1).toFloat() / 10.0;
      Blynk.virtualWrite(V20, tempThreshold); // Update Blynk App Slider
      Serial.print("Nextion Temp Threshold Update: "); Serial.println(tem
    }

    // If Nextion sends "H700" (meaning 70.0)
    if (nexData.startsWith("H")) {
      humThreshold = nexData.substring(1).toFloat() / 10.0;
      Blynk.virtualWrite(V21, humThreshold); // Update Blynk App Slider
      Serial.print("Nextion Hum Threshold Update: "); Serial.println(humTl
    }
  }
}

void setup() {
  // ... [Keep previous setup code: Serial, Wire, sensors, etc.] ...

  Blynk.begin(BLYNK_AUTH_TOKEN, modem, apn, "", "", "blynk.cloud", 80);
```

```
  // IMPORTANT: Pull the last saved thresholds from Blynk Cloud on startup
  Blynk.syncVirtual(V20, V21);

  timer.setInterval(10000L, sendAllData);
}

void loop() {
  Blynk.run();
  timer.run();
  checkNextionInput(); // Constantly listen for Display changes
}
```

Use code with caution.

2. How the Two-Way Sync Works

1. **From Phone to Screen:** When you move the slider on your phone, `BLYNK_WRITE` triggers. It updates the internal `tempThreshold` variable and then sends a command (`x1.val=...`) to the Nextion display. The screen updates instantly.
2. **From Screen to Phone:** When you change the value on the Nextion and trigger the `printf` event, the ESP32 receives the string in `checkNextionInput()`. It updates the internal variable and then calls `Blynk.virtualWrite(V20, ...)`. This pushes the value back to your phone, and the slider moves automatically.

3. Nextion "Touch Release" Event Reminder

Ensure your Nextion components **x1** and **x3** have these exact commands in their **Touch Release Event** window:

- **For x1:** `printf "T%d\n",x1.val`
- **For x3:** `printf "H%d\n",x3.val`

Would you like me to add a "Status Page" to the Nextion display that shows the 4G signal strength and Blynk connection status as well?

give me the whole code

This is the final, complete integrated code. It handles the **A7670C 4G modem**, **Airtel M2M APN**, **DS18B20**, **SHT45**, **7 Relays**, and the **bi-directional Nextion HMI** sync.

Hardware Mapping Summary

- **Modem (A7670C):** TX → GPIO 16, RX → GPIO 17
- **Nextion HMI:** TX → GPIO 32, RX → GPIO 33
- **DS18B20:** GPIO 4 (with 4.7k pull-up)
- **SHT45:** SDA (21), SCL (22)
- **Float Switch:** GPIO 13 (Pull-up mode)
- **Relays (NC):** GPIO 2, 12, 14, 15, 25, 26, 27

```

Use code with caution.

Nextion Configuration Note: Remember to set the **vvs1** property of `x0`, `x1`, `x2`, and `x3` to **1** in the Nextion Editor so the decimal points show up correctly.

How are you planning to **mount the ESP32 and A7670C**—on a custom PCB or a breadboard?

does this code have all the logics I told all the conditions I mentioned and the programming to do task as I mentioned ...

Yes, this code incorporates **every specific condition and logic** you requested. Here is a breakdown of how each requirement is programmed:

1. Interlocked Heater Logic

- **Condition:** Secondary heater only starts if the primary is already ON.
- **Implementation:** Inside `processLogic()`, `R_HEAT2` is nested within the `avgTemp < tempThreshold` check. If the Primary Heater (`R_HEAT1`) is killed by the high-temperature threshold, the Secondary Heater (`R_HEAT2`) is automatically forced `HIGH` (OFF).

2. Dual-Speed Fan & Safety Logic

- **Condition:** Secondary fan runs on low speed by default; switches to full speed if Temperature OR Humidity exceeds thresholds.
- **Implementation:**
  - `R_FAN2_HIGH` is wired to the High-Speed winding.
  - The logic `if (avgTemp > tempThreshold || hum > humThreshold)` triggers `R_FAN2_HIGH` to `LOW` (ON).
  - Simultaneously, it forces `R_HEAT1` and `R_HEAT2` to `HIGH` (OFF) for safety.

3. Bi-Directional Threshold Sync

- **Condition:** Change on Dashboard reflects on Screen, and change on Screen reflects on Dashboard.
- **Implementation:**
  - **Blynk → Nextion:** `BLYNK_WRITE(V20)` and `V21` send `x1.val` and `x3.val` commands to the display.
  - **Nextion → Blynk:** The `loop()` listens for `T` and `H` serial strings from the display and updates the Blynk virtual pins using `Blynk.virtualWrite`.
  - **Scaling:** The code uses the `* 10` and `/ 10` logic to handle Nextion's decimal

format.

4. Machine Components Logic

- **Work Light:** Controlled via **V10** (Blynk) and **bt0** (Nextion).
- **Tilt Up/Down:** Automated based on the Float Switch status (`LOW` for Empty, `HIGH` for Full).
- **Averaging:** Calculates `avgTemp` using both DS18B20 and SHT45 before making any decisions.

5. NC (Normally Closed) Hardware Safety

- **Condition:** If no current is provided (ESP32 off), the machine works.
- **Implementation:** The code uses `digitalWrite(pin, HIGH)` to **stop** the devices and `LOW` to **run** them, matching your NC relay wiring.

Final Verification of Virtual Pins:

- **V0/V1:** Temperatures
- **V2:** Humidity
- **V3:** Tank Status
- **V10:** Work Light
- **V20/V21:** Threshold Setpoints

Are you ready to **upload the code**, or should we double-check the **Nextion button object names** for the Work Light?

currently when I am adjusting the threshold from dashboard the change shows on the screen but not the other way around

If changes from the Blynk dashboard reflect on the Nextion screen but not the other way around, the Nextion display is likely not sending the correct data format to the ESP32. To fix this, you must ensure both the **Nextion Editor settings** and the **ESP32 code** are perfectly aligned.

1. The Nextion Editor Fix

The Nextion screen does not automatically send its value when you change it. You must tell it to "speak" to the ESP32.

1. Open your **Nextion Editor** and select the **x1** (Temp) or **x3** (Hum) component.
2. Go to the **Touch Release Event** tab.
3. Ensure the "Send Component ID" box is **unchecked** (we are sending custom text instead).
4. Enter the following exact code in the user code area:
   - **For x1:** `printf "T%d\n",x1.val`
   - **For x3:** `printf "H%d\n",x3.val`
5. **Compile** and re-upload the `.tft` file to your screen via SD card.

2. The ESP32 Code Fix

Ensure your `loop()` function is using a robust method to read the incoming serial string. Replace your existing `checkNextionInput()` or the `if (nexSerial.available())` block with this more reliable version:

cpp

```cpp
void loop() {
  Blynk.run();
  timer.run();

  // Robust Nextion Serial Listener
  if (nexSerial.available() > 0) {
    String nexData = nexSerial.readStringUntil('\n'); // Look for the \n s
    nexData.trim(); // Remove any hidden spaces or carriage returns

    if (nexData.length() > 0) {
      Serial.print("Raw Data from Nextion: ");
      Serial.println(nexData);

      if (nexData.startsWith("T")) {
        // Convert "T355" back to 35.5
        tempThreshold = nexData.substring(1).toFloat() / 10.0;

        Blynk.virtualWrite(V20, tempThreshold); // Update Dashboard Slide
        Serial.printf("New Temp Threshold: %.1f\n", tempThreshold);
      }
      else if (nexData.startsWith("H")) {
        // Convert "H700" back to 70.0
        humThreshold = nexData.substring(1).toFloat() / 10.0;
        Blynk.virtualWrite(V21, humThreshold); // Update Dashboard Slider
        Serial.printf("New Hum Threshold: %.1f\n", humThreshold);
      }
    }
  }
}
```

Use code with caution.

Why it might still fail:

- **Baud Rate:** Confirm that `nexSerial.begin(9600)` in your `setup()` matches the `bauds` setting in your Nextion project (usually 9600 by default).
- **Wiring:** Double-check that the Nextion **TX** pin is connected to ESP32 **GPIO 32 (RX1)**. If they aren't crossed correctly, the ESP32 will never receive the data.
- **Buffer Junk:** If you see "garbage" in the Serial Monitor when touching the screen, it means the Nextion is sending its standard "Touch Events" (hex codes) instead of the `printf` text. Re-check the **Touch Release Event** in the Editor.

When you touch the Nextion screen, do you see any text appear in your Arduino Serial Monitor?

also I have a few switches on the nextion display for different things to be operated via relay too and I need them on ...

To implement bi-directional control for additional relays using switches on both the

Nextion display and the **Blynk dashboard**, you must ensure that a change in one interface immediately triggers an update in the other.

The strategy involves using **Dual-State Buttons** (bt) on the Nextion and **Switch Widgets** on the Blynk dashboard, linked through the ESP32 logic.

1. Nextion Component Setup

In the **Nextion Editor**, for each relay switch (e.g., `bt1` for Relay 1, `bt2` for Relay 2, etc.):

- **Component Type:** Use a **Dual-State Button (bt)**.
- **Touch Release Event:** Add a `printf` command to send a unique identifier and the button's current value to the ESP32.
  - **For bt1 (Relay 1):** `printf "R1%d\n",bt1.val`
  - **For bt2 (Relay 2):** `printf "R2%d\n",bt2.val` Blynk Community +1

2. Blynk Datastream Setup

In the **Blynk Console**, create new **Virtual Pin** datastreams for each additional relay:

- **V11, V12, V13, etc.:** Set as **Integer** with a range of **0-1**.
- **Widget:** Use a **Switch** widget on the mobile or web dashboard linked to these pins. YouTube +1

3. Integrated Bi-Directional Code

Add the following logic to your existing ESP32 sketch to handle the new relays (using Relay 1 as an example).

cpp

```cpp
// --- BLYNK to ESP & NEXTION ---
// Triggered when you flip the switch on the Blynk App
BLYNK_WRITE(V11) {
  int state = param.asInt();
  digitalWrite(R_HEAT1, state); // Update physical relay

  // Update Nextion button state (bt1)
  nexSerial.print("bt1.val=" + String(state));
  nexSerial.write(0xff); nexSerial.write(0xff); nexSerial.write(0xff);
}

// --- NEXTION to ESP & BLYNK ---
// Part of the serial listener in your loop()
void checkNextionRelays(String nexData) {
  // If Nextion sends "R11" (Relay 1 ON) or "R10" (Relay 1 OFF)
  if (nexData.startsWith("R1")) {
    int state = nexData.substring(2).toInt();
    digitalWrite(R_HEAT1, state); // Update physical relay
    Blynk.virtualWrite(V11, state); // Sync Blynk Dashboard switch
  }
  // Repeat for R2, R3, etc.
}
```

Use code with caution.

4. Key Implementation Steps

- **Real-Time Feedback:** By using `Blynk.virtualWrite()` inside the Nextion listener, the dashboard switch will move automatically when you touch the screen.

Using ESP3
5 Jan 2024 –
welcome bac

- **Initial Sync:** Add `Blynk.syncVirtual(V11, V12, ...)` in your `setup()` to ensure the hardware and display match the last known state from the cloud upon booting.
- **Dual-State Icons:** In Nextion, you can use the `sta` attribute to change the button's appearance (e.g., different images for ON/OFF states) to provide clear visual feedback. Blynk Community +3

Would you like the **updated `loop()` and `checkNextionInput()`** functions with all 7 relays integrated for this bi-directional sync?

earlier the change on the threshold from dashboard was reflected on the screen too ...

If the bi-directional sync was working earlier but has stopped, it usually means the ESP32 is no longer "listening" to the Nextion Serial or the Blynk Cloud has lost the current state of the virtual pins.

To restore full two-way communication, we need to ensure the **Serial Buffer** is being cleared and that **Blynk** explicitly pulls the latest data at startup.

1. The "Resync" Logic for ESP32

Replace your current `loop()` and `setup()` sections with this code. It uses `Blynk.syncVirtual()` to pull thresholds from the cloud on boot and a more robust serial listener to catch Nextion changes.

cpp

```cpp
void setup() {
  Serial.begin(115200);
  nexSerial.begin(9600, SERIAL_8N1, RXD1, TXD1); // Nextion Serial

  // ... [Your existing sensor and relay setup] ...

  Blynk.begin(BLYNK_AUTH_TOKEN, modem, apn, "", "", "blynk.cloud", 80);

  // CRITICAL: This pulls the last saved V20/V21 values from Blynk to ESP
  // Then BLYNK_WRITE will automatically update the Nextion screen
  if (Blynk.connected()) {
    Blynk.syncVirtual(V20, V21, V10);
  }

  timer.setInterval(10000L, sendAllData);
}

void loop() {
  Blynk.run();
  timer.run();

  // ROBUST NEXTION LISTENER
  if (nexSerial.available() > 0) {
    String nexData = nexSerial.readStringUntil('\n');
    nexData.trim(); // Remove any hidden \r or spaces

    if (nexData.startsWith("T")) {
      tempThreshold = nexData.substring(1).toFloat() / 10.0;
      Blynk.virtualWrite(V20, tempThreshold); // Update Phone
```

      humThreshold = nexData.substring(1).toFloat() / 10.0;
      Blynk.virtualWrite(V21, humThreshold); // Update Phone
      Serial.print("Nextion -> Blynk Hum: "); Serial.println(humThreshold
    }
  }
}
```

Use code with caution.

2. Verify Nextion "Touch Release"

The most common reason for the "Nextion-to-Blynk" failure is the display not sending the string. Ensure your **x1** and **x3** components have these exact lines in their **Touch Release Event**:

- **For x1:** `printf "T%d\n",x1.val`
- **For x3:** `printf "H%d\n",x3.val`
- **Note:** Ensure the "Send Component ID" checkbox is **UNCHECKED**.

3. Troubleshooting Checklist

- **Serial Buffer:** If the ESP32 is busy with 4G communication, the Nextion data might get "stuck" in the buffer. The `nexData.trim()` and `readStringUntil('\n')` help clear this.
- **Blynk Flood Error:** If you change thresholds too fast, Blynk might temporarily disconnect you. Ensure you aren't clicking the Nextion buttons more than once per second.
- **Wiring:** Check if the wire between **Nextion TX** and **ESP32 Pin 32** is loose. Since Dashboard -> Screen works, the ESP32 TX wire is fine, but the **return path** (Nextion TX) might be broken.

When you move the slider on your phone, does the Serial Monitor show any activity, or is it completely silent?

where do I find the send component id checkbox

In the **Nextion Editor**, you can find the **Send Component ID** checkbox **in the Event pane (usually located at the bottom right of the screen)**.

Steps to find it:

1. **Click on your component** (e.g., `x1` or `x3`) in the Canvas/Display area.
2. Look at the bottom right window labeled **Event**.
3. You will see two tabs: **Touch Press Event** and **Touch Release Event**.
4. The checkbox is located just above the text box where you type your `printf` code.
   - **It must be UNCHECKED** for your custom `printf` commands to work properly without interference.

Why this matters:

If it is **checked**, Nextion sends a hidden Hexadecimal code (0x65...) every time you touch the component. This "junk" data confuses the ESP32, which is waiting for the clean text string starting with "T" or "H".

Also check the "vvs1" property:

While you are in the Editor, click on your `x1` or `x3` component and look at the **Attribute** pane (bottom left):

- Find the property **vvs1**.
- Set it to **1**. This ensures the display shows `35.5` instead of `355`.

Are you able to see the Event pane now, or is it hidden behind another window?

the printf command throws an error but the prints works

If the `printf` command is throwing an error in your Nextion Editor, it's likely because your specific Nextion model (like the **Basic Series**) does not support the `printf` instruction, which is typically reserved for **Intelligent Series** models. Nextion +1

You can achieve the same result using the standard `print` command by sending the parts of your message sequentially.

1. Updated Nextion Editor Events

Replace the `printf` code in your **Touch Release Event** for **x1** and **x3** with these `print` sequences.

- **For x1 (Temperature Threshold):**

```c
print "T"       // Send the identifier
print x1.val    // Send the numeric value (e.g., 355)
```

```
printh 0a       // Send the newline character (\n) for the ESP32 to det
```

Use code with caution.

- **For x3 (Humidity Threshold):**

```c
print "H"       // Send the identifier
print x3.val     // Send the numeric value
printh 0a        // Send the newline character (\n)
```

Use code with caution.

- **For Relay Buttons (e.g., bt1):**

```c
print "R1"      // Send the Relay 1 identifier
print bt1.val    // Send the state (0 or 1)
printh 0a        // Send the newline character (\n)
```

Use code with caution.

2. Why this works

Nextion's `print` command sends the raw ASCII value of whatever follows it. By printing the letter "T", then the value, and finally the hex code `0a` (which is the ASCII for `\n`), you create the exact same string (`T355\n`) that the `printf` command would have generated. nextion.ca

3. ESP32 Code Compatibility

The ESP32 code remains the same because it is still looking for that `\n` to end the string:

```cpp
if (nexSerial.available() > 0) {
    String nexData = nexSerial.readStringUntil('\n'); // Detects the prin
    nexData.trim();

    if (nexData.startsWith("T")) {
      tempThreshold = nexData.substring(1).toFloat() / 10.0;
      Blynk.virtualWrite(V20, tempThreshold);
    }
    // ... rest of the logic
}
```

Use code with caution.

Pro-Tip for Nextion

If you have many buttons, ensure each one has the `printh 0a` at the end of its code block. Without this, the ESP32 will keep waiting and won't realize the command has

Nextion

Does the "T" and "H" data show up in your Serial Monitor now when you use the `print` and `printh` commands?

ok done with that now give me the whole code with everything

This is the **complete, final master code**. It integrates the **A7670C 4G Modem**, **Airtel M2M Sync**, **DS18B20**, **SHT45**, **Float Switch**, **7 NC Relays**, and the **Bi-directional Nextion HMI** (using the `print` + `printh 0a` method).

Master Wiring Reference

- **Modem (A7670C):** TX → 16, RX → 17
- **Nextion HMI:** TX → 32, RX → 33 (Nextion Editor: `print "T"`, `print x1.val`, `printh 0a`)
- **Sensors:** DS18B20 (GPIO 4 + 4.7k resistor), SHT45 (SDA 21, SCL 22), Float Switch (GPIO 13)
- **Relays (NC):** GPIO 2, 12, 14, 15, 25, 26, 27 (**LOW = ON**, **HIGH = OFF**)

      digitalWrite(R_LIGHT, lightVal);
      Blynk.virtualWrite(V10, lightVal);
    }
  }

}
```

Use code with caution.

Final Nextion Reminder: For the Work Light button (`bt0`) to sync back to the phone, use `print "L"`, `print bt0.val`, and `printh 0a` in its **Touch Release Event**.

Do you have any other **machine components** like a buzzer or alarm that should trigger if the tank stays empty for too long?

when I change the threshold from the dashboard it shows on the display but when I do the opposite it dosent show up on display

This "one-way" sync usually happens because the Nextion isn't sending the data in a format the ESP32 can understand, or the ESP32 is too busy to "hear" the display. To fix this, you must adjust both the **Nextion Editor** settings and the **ESP32 loop**.

1. Fix the Nextion Editor (Screen to ESP)

The screen won't send the value unless you explicitly tell it to. For your **x1** and **x3** components:

1. **Select the Component**: Click on `x1` (Temp) or `x3` (Hum) in the Nextion Editor.
2. **Touch Release Event**: In the bottom-right **Event** window, ensure the **"Send**

Component ID" box is **UNCHECKED**.

3. **Add the Print Code**: In the user code area, enter:
   - **For x1**: `print "T"`, then `print x1.val`, then `printh 0a`
   - **For x3**: `print "H"`, then `print x3.val`, then `printh 0a`

4. **Re-upload**: Compile and upload this updated `.tft` file to your screen.

2. Update the ESP32 Loop (ESP to Dashboard)

The ESP32 needs to be listening specifically for those "T" and "H" markers. Ensure your `loop()` contains this robust listener:

cpp

```cpp
void loop() {
  Blynk.run();
  timer.run();

  // Bi-directional Listener
  if (nexSerial.available() > 0) {
    // Read the incoming string until the newline (printh 0a)
    String nexData = nexSerial.readStringUntil('\n');
    nexData.trim(); // Clean up hidden spaces

    if (nexData.startsWith("T")) {
      // Scale back to float (e.g., 355 becomes 35.5)
      tempThreshold = nexData.substring(1).toFloat() / 10.0;
      Blynk.virtualWrite(V20, tempThreshold); // Sync the Dashboard Slide
    }
    else if (nexData.startsWith("H")) {
      humThreshold = nexData.substring(1).toFloat() / 10.0;
      Blynk.virtualWrite(V21, humThreshold); // Sync the Dashboard Slider
    }
  }
}
```

Use code with caution.

3. Why Dashboard -> Screen works but not vice-versa:

- **Command vs. Listener**: When you change the Dashboard, the ESP32 **commands** the Nextion to change (e.g., `x1.val=355`). The Nextion obeys instantly.
- **The Silent Screen**: When you change the Screen, the Nextion is **silent** by default. It doesn't tell the ESP32 anything unless you use the `print` commands mentioned in Step 1.
- **Scaling**: If you see values like `355` instead of `35.5` on the dashboard, ensure you are dividing by `10.0` in the ESP32 code.

After updating the Nextion Editor with the `print` commands, do you see the values changing on your phone?

I did uploaded the commands on the nextion editor and then compiled and uploaded the new .tft and also used the last ...

If the threshold changes from your phone reflect on the screen but not vice versa, the **return path** (from Nextion to ESP32) is failing. This is almost always caused by a missing **termination character** or the **ESP32 Serial buffer** getting out of sync.

To fix this, we need to ensure the Nextion sends a clear "End of Message" signal and the ESP32 is actively listening for it. Nextion +1

1. The Nextion Editor Fix (Critical)

The Nextion `print` command sends raw text, but the ESP32 doesn't know when that text ends unless you send a **newline character (`\n`)**. In the Nextion Editor, your **Touch Release Event** for `x1` and `x3` must look exactly like this:

- **For x1 (Temperature Threshold):**

```c
print "T"        // Step 1: Send the identifier
print x1.val     // Step 2: Send the numeric value (e.g., 355)
printh 0a        // Step 3: Send the NEWLINE character (Hex 0x0A)
```

Use code with caution.

- **For x3 (Humidity Threshold):**

```c
print "H"
print x3.val
printh 0a        // Crucial: This tells the ESP32 "Message is finished"
```

Use code with caution.

- **Checkbox:** Ensure the **"Send Component ID"** box is **UNCHECKED**. If checked, it sends extra junk data that breaks the communication. YouTube +1

2. The ESP32 "Listener" Fix

Update your `loop()` to be more aggressive in catching these messages. We will add a **Timeout** and **Debug Prints** so you can see exactly what the ESP32 is "hearing" in the Arduino Serial Monitor.

```cpp
void loop() {
  Blynk.run();
  timer.run();

  // --- DEBUGGING: Check if Nextion is sending ANYTHING ---
  if (nexSerial.available() > 0) {
    // Read until the '\n' (which is the 'printh 0a' we sent)
    String nexData = nexSerial.readStringUntil('\n');
    nexData.trim(); // Clean up hidden spaces

    Serial.print("Nextion Received: ");
    Serial.println(nexData); // This will show up in your PC Serial Monitc

    if (nexData.startsWith("T")) {
      // Convert "T355" back to 35.5
```

```
      tempThreshold = nexData.substring(1).toFloat() / 10.0;
      Blynk.virtualWrite(V20, tempThreshold); // Update Phone Slider
      Serial.println("Updated Blynk Temp Threshold!");
    }
    else if (nexData.startsWith("H")) {
      humThreshold = nexData.substring(1).toFloat() / 10.0;
      Blynk.virtualWrite(V21, humThreshold); // Update Phone Slider
      Serial.println("Updated Blynk Hum Threshold!");
    }
  }
}
```

Use code with caution.

3. Connection & Hardware Troubleshooting

- **TX/RX Cross:** Since Dashboard → Screen works, your **ESP32 TX (33)** wire is fine. Check the **Nextion TX to ESP32 RX (32)** wire. If it's loose, the ESP32 will never receive data from the screen.
- **Common Ground:** Ensure the **GND** of the Nextion is connected to the **GND** of the ESP32. Without this, the signals become "noise".
- **Serial Monitor Test:** Open your **Arduino Serial Monitor** (115200 baud). When you touch the Nextion button, do you see `Nextion Received: T355` appear?
  - **If NO:** The Nextion isn't sending data (check Editor code/wiring).
  - **If YES but Phone doesn't update:** There is a Blynk connection issue or a virtual pin mismatch. Blynk Community +4

Can you confirm if you see the "Nextion Received" text in your Serial Monitor when you touch the screen?

I have checked the connections and now give me the entire code with showing everything on the serial monitor too

This final version includes **extra debug prints** to show exactly what is happening between the **4G Modem**, the **Nextion Display**, and the **Blynk Cloud**.

Master Troubleshooting Tip

If the Screen-to-Phone sync still fails, look at the **Serial Monitor**.

- If you see `Raw from Nextion: T355`, the wiring and Nextion code are perfect.
- If you see `Raw from Nextion: Ì` (garbage), the **Nextion Baud rate** is wrong (try 9600 or 115200).

        Serial.print("Update -> Hum Threshold: "); Serial.println(humThres
      }
    }
  }
}
```

Use code with caution.

When you touch the Nextion screen, do you see **"Raw from Nextion: T..."** appear in the **Serial Monitor** now?

System Ready.
Blynk -> Temp Threshold Update: 60.00...

The Serial Monitor output confirms two things:

1. **Wiring is Correct:** The ESP32 is receiving data from the Nextion (you see `Raw from Nextion`).
2. **Baud Rate/Encoding Error:** The "garbage" characters (`ï¿½ï¿½ï¿½`) and weird strings like `HUP6` and `TDNz` mean the Nextion is sending data at a **different speed** or sending **Hexadecimal Touch Events** instead of the clean text we programmed.

1. Fix the Nextion Editor (The "Garbage" Cause)

Nextion sends a "Touch Event" (3 to 7 bytes of hex code) by default. Your ESP32 is trying to read those as text, which is why it looks like junk.

In the Nextion Editor:

1. Click on **x1** and **x3**.
2. Look at the **Touch Release Event**.
3. **UNCHECK** the box that says **"Send Component ID"**. (This stops the `ï¿½ï¿½ï¿½` junk).
4. Ensure your code is exactly this (one command per line):

```c
print "T"
print x1.val
printh 0a
```

Use code with caution.

5. **Re-compile** and **Re-upload** the `.tft` file.

2. Match the Baud Rate

If you still see junk after unchecking the box, your Nextion might be set to 115200 while the ESP32 is at 9600.

Option A (Change ESP32):
Change this line in `setup()` to match the standard high speed:

```cpp
nexSerial.begin(115200, SERIAL_8N1, RXD1, TXD1);
```

Use code with caution.

Option B (Verify Nextion):
Click on an empty area of your Nextion page and check the `bauds` attribute in the bottom left. It should be `9600`.

3. Software Workaround (Ignore Junk)

Update your `loop` to ignore those hex bytes and only look for our "T" or "H" markers:

```cpp
void loop() {
  Blynk.run();
  timer.run();

  if (nexSerial.available() > 0) {
    // Read the string
    String nexData = nexSerial.readStringUntil('\n');

    // Check if it actually contains our identifier
    if (nexData.indexOf('T') != -1) {
      int pos = nexData.indexOf('T');
      tempThreshold = nexData.substring(pos + 1).toFloat() / 10.0;
      Blynk.virtualWrite(V20, tempThreshold);
      Serial.print("SUCCESS! Temp set to: "); Serial.println(tempThreshol
    }
    else if (nexData.indexOf('H') != -1) {
      int pos = nexData.indexOf('H');
      humThreshold = nexData.substring(pos + 1).toFloat() / 10.0;
      Blynk.virtualWrite(V21, humThreshold);
      Serial.print("SUCCESS! Hum set to: "); Serial.println(humThreshold);
    }
  }
}
```

Use code with caution.

Try unchecking the "Send Component ID" box first. Does the Serial Monitor show clean "T" and "H" letters after that?

Next Step: Check the **Nextion Editor** for the "Send Component ID" checkbox.

I have already unchecked it

The "garbage" characters (`ï¿½ï¿½ï¿½`) in your Serial Monitor prove that the ESP32 is receiving data, but it can't "read" it because of a **Baud Rate Mismatch** or **Nextion encoding**. Even if you unchecked "Send Component ID," Nextion still sends a "Ready" or "Touch" code in a format the ESP32 sees as junk. Arduino Forum +2

To fix this for good, we will use a **Filter** to ignore the junk and only look for your "T" or "H" commands.

1. Fix the Nextion Editor (Correct Code)

The Nextion `print` command sends the **raw value** of a number, not the text "355". To send "355" as text so the ESP32 can read it, you must use the `prints` command for the variable.

In the Nextion Touch Release Event:

- **For x1 (Temp):**

```c
print "T"
prints x1.val,0  // 'prints' sends the number as text characters
printh 0a        // Newline marker
```

Use code with caution.

- **For x3 (Hum):**

```c
print "H"
prints x3.val,0
printh 0a
```

Use code with caution.

2. Update the ESP32 `loop()`

Use this logic to filter out the `ï¿½ï¿½ï¿½` junk. It searches the incoming data for the letter **T** or **H** and ignores everything else. Stack Overflow

```cpp
```

```
void loop() {
  Blynk.run();
  timer.run();

  if (nexSerial.available() > 0) {
    String nexData = nexSerial.readStringUntil('\n');

    // DEBUG: See exactly what's coming in
    Serial.print("Filtered Data: "); Serial.println(nexData);

    // 1. Look for Temperature Threshold
    if (nexData.indexOf('T') != -1) {
      int tPos = nexData.indexOf('T');
      String valStr = "";
      // Extract only digits after 'T'
      for(int i = tPos + 1; i < nexData.length(); i++) {
        if(isDigit(nexData[i])) valStr += nexData[i];
      }
      if(valStr.length() > 0) {
        tempThreshold = valStr.toFloat() / 10.0;
        Blynk.virtualWrite(V20, tempThreshold);
        Serial.printf("SYNC SUCCESS: Temp Threshold set to %.1f\n", tempTl
      }
    }

    // 2. Look for Humidity Threshold
    else if (nexData.indexOf('H') != -1) {
      int hPos = nexData.indexOf('H');
      String valStr = "";
      for(int i = hPos + 1; i < nexData.length(); i++) {
        if(isDigit(nexData[i])) valStr += nexData[i];
      }
      if(valStr.length() > 0) {
        humThreshold = valStr.toFloat() / 10.0;
        Blynk.virtualWrite(V21, humThreshold);
        Serial.printf("SYNC SUCCESS: Hum Threshold set to %.1f\n", humThre
      }
    }
  }
}
```

Use code with caution.

3. Connection Checklist

- **Common Ground:** Double-check that a wire connects the **GND** of the Nextion to the **GND** of the ESP32.
- **Voltage:** If your Nextion is the 5V version, use a **voltage divider** (two resistors) on the Nextion TX line to drop it to 3.3V before it hits the ESP32 Pin 32, otherwise, the signals might be "noisy". GitHub +1

After switching to `prints x1.val,0` in the Nextion Editor, do the numbers look clear in the Serial Monitor?

give me the entire code for esp32 with this change

This version includes the **Digital Filter** in the `loop()` to clean out the Nextion "garbage" characters and the refined `prints` logic support. It ensures that even if the Nextion sends extra hex codes, the ESP32 only picks out the **T** (Temperature) and **H** (Humidity) values.

      }
    }
  }
}
```

Use code with caution.

Reminder for Nextion Editor

Ensure you use the **`prints`** command instead of just `print` for the values:

- `print "T"`
- `prints x1.val,0`
- `printh 0a`

Does the **"Nextion Sync"** message now appear correctly in your **Serial Monitor** when you adjust the screen?

the x1 and x3 are float value controller that are controlled by other switches on the nextion display

If **x1** and **x3** are being updated by other buttons on the Nextion (like "+" or "-" buttons),

the Nextion still needs to "shout" the new value to the ESP32 whenever those switches are pressed.

1. Nextion Editor Update

For **every button** on your Nextion display that changes the value of `x1` or `x3`, you must add the following lines at the **end** of its "Touch Release Event" code:

For buttons affecting x1 (Temperature):

```c
// ... existing logic to change x1.val ...
print "T"
prints x1.val,0
printh 0a
```

Use code with caution.

For buttons affecting x3 (Humidity):

```c
// ... existing logic to change x3.val ...
print "H"
prints x3.val,0
printh 0a
```

Use code with caution.

---

2. Final ESP32 Code (Optimized)

This code uses a more robust "Digit Extractor" to ensure that if Nextion sends any background junk along with the value, the ESP32 only picks out the numbers.

```cpp
#define BLYNK_TEMPLATE_ID "TMPL3z0OuMdNy"
#define BLYNK_TEMPLATE_NAME "try01"
#define BLYNK_AUTH_TOKEN "Wf5Ze5ZhyWuGEa_qNFpVUaLR4v_r_Acj"

#define TINY_GSM_MODEM_SIM7600
#define BLYNK_PRINT Serial

#include <Wire.h>
#include <Adafruit_SHT4x.h>
#include <OneWire.h>
#include <DallasTemperature.h>
#include <TinyGsmClient.h>
#include <BlynkSimpleTinyGSM.h>

// Pins
#define SENSOR_PIN 4
#define FLOAT_SWITCH 13
#define RXD2 17         // GSM RX
#define TXD2 16         // GSM TX
#define RXD1 32         // Nextion RX
#define TXD1 33         // Nextion TX

// Relays
```

```
const int R_LIGHT = 2, R_HEAT1 = 12, R_HEAT2 = 14, R_TILT_UP = 15, R_TILT_

}

void loop() {
  Blynk.run();
  timer.run();

  if (nexSerial.available() > 0) {
    String nexData = nexSerial.readStringUntil('\n');
    Serial.print("Nextion Buffer: "); Serial.println(nexData);

    char type = ' ';
    if (nexData.indexOf('T') != -1) type = 'T';
    else if (nexData.indexOf('H') != -1) type = 'H';

    if (type != ' ') {
      String valStr = "";
      for(int i = nexData.indexOf(type) + 1; i < nexData.length(); i++) {
        if(isDigit(nexData[i])) valStr += nexData[i];
      }
      if(valStr.length() > 0) {
        float val = valStr.toFloat() / 10.0;
        if (type == 'T') { tempThreshold = val; Blynk.virtualWrite(V20, te
        else { humThreshold = val; Blynk.virtualWrite(V21, humThreshold);
        Serial.println(val);
      }
    }
  }

}
```

Use code with caution.

3. Verification

When you press a "+" or "-" button on the Nextion:

1. Check the **Serial Monitor**. It should now show `Nextion Buffer: ...T355...` and then `Temp Set: 35.5`.
2. If it works in Serial Monitor, the **Blynk Slider** should move automatically.

Does the "Nextion Buffer" line in Serial Monitor now show the 'T' or 'H' when you press those adjustment switches?

Nextion Buffer: □
Nextion Buffer: □□□□□□H...

The garbage characters (`ï¿½ï¿½ï¿½`) in your Serial Monitor confirm that the ESP32 is receiving data, but it cannot decode it because of a **Baud Rate Mismatch** or **Nextion encoding**. Even with "Send Component ID" unchecked, Nextion sends standard "Return Data" (like hex codes for touch events) that the ESP32 interprets as junk if not filtered correctly. Athanasios Seitanis +2

1. Fix the Nextion Editor (Correct Logic)

The `print` command sends the **raw numeric value** (binary), which the ESP32 reads as junk. To send "355" as readable text characters, you must use `prints`. Athanasios Seitanis

In the Nextion Touch Release Event:

- **For x1 (Temp):**

```c
print "T"
prints x1.val,0  // Sends "355" as characters '3','5','5'
printh 0a        // Newline marker \n
```

Use code with caution.

- **For x3 (Hum):**

```c
print "H"
prints x3.val,0
printh 0a
```

Use code with caution.

2. Complete ESP32 Master Code

This version uses a robust filter that specifically ignores the `ï¿½ï¿½ï¿½` junk and only extracts numbers following your **'T'** or **'H'** markers. Stack Overflow

  nexSerial.print("b9.txt=\"" + String((tankStatus == LOW) ? "EMPTY" : "F

  // Sync to Blynk
  Blynk.virtualWrite(V0, dsTemp); Blynk.virtualWrite(V1, shtTemp);
  Blynk.virtualWrite(V2, shtHum); Blynk.virtualWrite(V3, (tankStatus == LO
}

void setup() {
  Serial.begin(115200);
  for (int i=0; i<7; i++) { pinMode(relayPins[i], OUTPUT); digitalWrite(re
  pinMode(FLOAT_SWITCH, INPUT_PULLUP);
  Wire.begin();
  if (sht4.begin()) shtFound = true;
  sensors.begin();

  // Try 9600 first; if still junk, change to 115200 to match screen baud
  nexSerial.begin(9600, SERIAL_8N1, RXD1, TXD1);
  simSerial.begin(115200, SERIAL_8N1, RXD2, TXD2);

  delay(5000);
```

```
  Blynk.begin(BLYNK_AUTH_TOKEN, modem, apn, "", "", "blynk.cloud", 80);
  Blynk.syncVirtual(V20, V21, V10);
  timer.setInterval(10000L, sendAllData);
  Serial.println("System Ready.");
}

void loop() {
  Blynk.run();
  timer.run();

  if (nexSerial.available() > 0) {
    String nexData = nexSerial.readStringUntil('\n');

    char type = ' ';
    if (nexData.indexOf('T') != -1) type = 'T';
    else if (nexData.indexOf('H') != -1) type = 'H';

    if (type != ' ') {
      String valStr = "";
      // Filter out garbage: only extract digits after the marker
      for(int i = nexData.indexOf(type) + 1; i < nexData.length(); i++) {
        if(isDigit(nexData[i])) valStr += nexData[i];
      }
      if(valStr.length() > 0) {
        float val = valStr.toFloat() / 10.0;
        if (type == 'T') { tempThreshold = val; Blynk.virtualWrite(V20, te
        else { humThreshold = val; Blynk.virtualWrite(V21, humThreshold);
        Serial.printf("SYNC SUCCESS: %c Threshold set to %.1f\n", type, va
      }
    }
  }
}
```

Use code with caution.

3. Connection Checklist

- **Common Ground**: Ensure a solid wire connects the **GND** of the Nextion to the **GND** of the ESP32.
- **Baud Rate**: If you still see garbage, change `nexSerial.begin(9600)` to `115200` in the code.
- **Power**: Ensure the Nextion is powered by an **external 5V supply**, not the ESP32 pin. OceanLabz +1

After uploading the code and updating the Nextion Editor, does the "SYNC SUCCESS" message appear in the Serial Monitor?

extion Buffer: □
Nextion Buffer: □...

The constant stream of garbage characters (`ï¿½ï¿½ï¿½`) even when you aren't touching the display is a classic sign of **electrical noise**, **floating pins**, or a **baud rate mismatch** between the ESP32 and the Nextion.

ESP32 hard
characters
2 Nov 2024 -
replied that t
Stack O

1. Fix the "Phantom" Data (Floating RX Pin)

If you see junk even when not touching the screen, the ESP32's RX pin (GPIO 32) is likely "floating" and picking up electrical interference from your A7670C 4G module or power lines. Arduino Forum

- **Action:** Connect a **10kΩ pull-up resistor** between **GPIO 32 (ESP32 RX)** and the **3.3V pin** on the ESP32. This keeps the line stable when no data is being sent.
- **Alternative:** Ensure your **GND connection** between the Nextion and ESP32 is very short and secure. A loose ground is the most common cause of serial "phantom" data. Campus Component

2. Check for Baud Rate Mismatch

If the ESP32 is listening at 9600 but the Nextion is sending at a different speed (like 115200), it will interpret idle noise as junk characters. OceanLabz

- **Action:** In your `setup()`, ensure `nexSerial.begin(9600)` matches the `bauds` setting in your Nextion Editor project.
- **Pro-Tip:** Some Nextion displays have a default startup message. You can ignore the first few seconds of data using a delay in your code. YouTube +1

3. Identify Electrical Interference

The **A7670C 4G module** creates massive electromagnetic interference (EMI) when it communicates with cell towers.

- **Action:** Move the serial wires for the Nextion display as far away as possible from the 4G module's antenna and power wires.
- **Action:** Use **twisted-pair wires** for the Nextion TX/RX lines to reduce noise pickup. Arduino Forum

4. Logic Fix in the Code

To stop the "garbage" from triggering your logic, update your `loop` to strictly ignore any message that doesn't start with your specific identifiers ('T' or 'H').

cpp

```cpp
void loop() {
  Blynk.run();
  timer.run();

  if (nexSerial.available() > 0) {
    // Read the incoming data
    String nexData = nexSerial.readStringUntil('\n');
    nexData.trim();

    // ONLY process if it contains our specific markers
    if (nexData.indexOf('T') != -1 || nexData.indexOf('H') != -1) {
       Serial.print("Valid Nextion Command: ");
       Serial.println(nexData);
       // ... existing logic to update thresholds ...
    } else {

       // Optional: Debug junk to see what it is
       // Serial.print("Ignored Junk: "); Serial.println(nexData);
    }
  }
}
```

Use code with caution.

Arduino

Summary of Physical Fixes:

1. **Add a 10kΩ pull-up resistor** to GPIO 32.
2. **Shorten your GND wires** and ensure they are all connected to a single point.
3. **Separate your 4G antenna** from your serial data wires.

Does adding the 10kΩ pull-up resistor to the ESP32 RX pin stop the constant stream of junk?

Nextion Buffer: □►►►HUP□
Nextion Buffer: □►►►...

The garbage characters you are seeing (`ï¿½ï¿½ï¿½`) are actually **Hexadecimal Return Data** sent by the Nextion display by default. Even if you unchecked "Send Component ID," the display still sends a specific 7-byte sequence whenever a touch event occurs (starting with `0x65`). Your ESP32 tries to read these binary bytes as text, which results in "noise" on your Serial Monitor. Arduino Forum +4

To fix this, you must update your code to **ignore the binary junk** and only look for your specific text commands (`HUP` and `HDN`).

1. Updated ESP32 Logic (The "Garbage" Filter)

Replace your serial listener in the `loop()` with this version. It scans the incoming data for your specific keywords and discards everything else.

cpp

```cpp
void loop() {
  Blynk.run();
  timer.run();

  if (nexSerial.available() > 0) {
    // Read the incoming data into a string
    String nexData = nexSerial.readString();

    // 1. Check for 'HUP' (Ignoring the ï¿½ï¿½ï¿½ junk before it)
    if (nexData.indexOf("HUP") != -1) {
      Serial.println("Command Received: TILT UP");
      // Add your Tilt Up logic here
      Blynk.virtualWrite(V13, 1);
    }

    // 2. Check for 'HDN'
    else if (nexData.indexOf("HDN") != -1) {
      Serial.println("Command Received: TILT DOWN");
      // Add your Tilt Down logic here
      Blynk.virtualWrite(V14, 1);
    }

    // 3. Clear the buffer to prevent "ghost" triggers
    while(nexSerial.available()) nexSerial.read();
  }
}
```

Use code with caution.

2. Nextion Editor Refinement

To make the signal even cleaner, ensure your buttons on the Nextion use the `prints` command to send the text explicitly. In the **Touch Release Event** for your buttons:

- **For UP Button:**

```c
prints "HUP",0  // Sends only the characters H, U, P
printh 0a       // Sends the newline character for the ESP32
```

Use code with caution.

- **For DOWN Button:**

```c
prints "HDN",0
printh 0a
```

Use code with caution.

3. Why the noise persists

- **Return Codes:** Nextion always sends a status byte (like `0x65` for touch) unless you use a library that specifically suppresses it.
- **Power Noise:** Nextion displays inject significant electrical noise into the power lines. Ensure you have a **470uF capacitor** across the Nextion's 5V and GND pins to stabilize the signal.
- **Baud Rate:** If the "garbage" characters never stop even when not touching the screen, double-check that your `nexSerial.begin(9600)` exactly matches the `bauds` setting in your Nextion project. Arduino Forum +3

Does the **"Command Received"** message now show up clearly in your Serial Monitor when you click the buttons?

I a not changing the nextion rn just give the entire code with the garbage handling and also make sure to print the relays ...

To stop the garbage characters and ensure your system is fully transparent, we will use a **Marker-Based Serial Filter**.

Instead of reading everything the Nextion sends (including its internal 7-byte hex "junk" codes), the code below will only "listen" for data that starts with your specific characters (**T, H, L, R**). It also includes a secondary timer that prints a clear **Relay Status Report** to your Serial Monitor every 5 seconds.

  for (int i=0; i<7; i++) { pinMode(relayPins[i], OUTPUT); digitalWrite(re
  pinMode(FLOAT_SWITCH, INPUT_PULLUP);
  Wire.begin();
  if (sht4.begin()) shtFound = true;
  sensors.begin();
  simSerial.begin(115200, SERIAL_8N1, RXD2, TXD2);
  nexSerial.begin(9600, SERIAL_8N1, RXD1, TXD1);
  delay(5000);
  Blynk.begin(BLYNK_AUTH_TOKEN, modem, apn, "", "", "blynk.cloud", 80);
  Blynk.syncVirtual(V20, V21, V10);

  timer.setInterval(10000L, sendAllData);
  timer.setInterval(5000L, printRelayStatus); // Every 5 seconds
}

void loop() {
  Blynk.run();
  timer.run();

  // --- NEXTION GARBAGE HANDLING ---
  if (nexSerial.available() > 0) {
    String nexData = nexSerial.readStringUntil('\n');
    nexData.trim();

    // Only process if the string contains our valid markers
    if (nexData.indexOf('T') != -1 || nexData.indexOf('H') != -1 || nexDat
```

```
      Serial.print("Nextion Command: "); Serial.println(nexData);

      if (nexData.startsWith("T")) {
        tempThreshold = nexData.substring(1).toFloat() / 10.0;
        Blynk.virtualWrite(V20, tempThreshold);
      }
      else if (nexData.startsWith("H")) {
        humThreshold = nexData.substring(1).toFloat() / 10.0;
        Blynk.virtualWrite(V21, humThreshold);
      }
    }
    // Any hex junk like ï¿½ï¿½ï¿½ is simply ignored because it doesn't c
  }
}
```

Use code with caution.

Key Changes

1. **Garbage Filter**: Added `if (nexData.indexOf('T') != -1 || ...)` inside the `loop`. This ignores any serial data that doesn't include your defined command markers, keeping the logic safe from hex junk.
2. **Status Timer**: Added `timer.setInterval(5000L, printRelayStatus)`. This will print a formatted list of all 7 relays and their current state (Working vs. Stopped) every 5 seconds.
3. **Relay Logic Context**: Corrected the serial prints to reflect **NC (Normally Closed)** logic—when the pin is `LOW`, the report will correctly state the device is "WORKING". Arduino Forum +2

After you upload this, open the Serial Monitor (115200) and wait 5 seconds. Does the relay report appear clearly?

I am seeing the HUP and TUP but the dashboard dosent change

If you see **HUP** and **TUP** in your serial monitor but the **Blynk dashboard** is not updating, it means **the ESP32 is successfully receiving commands from the Nextion display but is failing to transmit that data to the Blynk cloud**.

1. Fix the "Manual Trigger" in Code

For the dashboard to reflect changes made on the physical display, you must explicitly call `Blynk.virtualWrite()` immediately after the ESP32 processes the Nextion command. Blynk Community +1

Update your `loop()` to include these sync lines:

cpp

```cpp
if (nexData.startsWith("TUP")) {
    tempThreshold += 0.5; // Example logic for incrementing
    Blynk.virtualWrite(V20, tempThreshold); // <--- THIS UPDATES THE DASHB
    Serial.println("Temp Up: Dashboard Updated");
}
if (nexData.startsWith("HUP")) {
    humThreshold += 1.0;
```

Reddit ·

```
    Blynk.virtualWrite(V21, humThreshold); // <--- THIS UPDATES THE DASHB
    Serial.println("Hum Up: Dashboard Updated");
}
```

Use code with caution.

2. Check GSM Connection Status

If `Blynk.virtualWrite()` is in your code but nothing happens, your GSM module may have lost its connection to the Blynk server. Blynk Community +1

- **Verify the Auth Token**: Ensure the token in your code exactly matches the one in **Device Info** on your web console.
- **Force Cloud Connection**: In your `Blynk.begin()`, specify the server and port explicitly for GSM modules.

cpp

```
Blynk.begin(BLYNK_AUTH_TOKEN, modem, apn, "", "", "blynk.cloud", 80);
```

Use code with caution.

- **Avoid "Flood Error"**: Ensure you are not sending these updates too fast. If you send more than **10 values per second**, Blynk will temporarily disconnect your device. Blynk Community +2

3. Dashboard Widget Configuration

If the hardware is sending data but the dashboard stays still:

- **Check Pin Assignments**: Ensure the **Virtual Pin** (e.g., V20) in your code matches the pin assigned to the widget (Gauge, Slider, or Value Display) in the Blynk Web Console.
- **Reading Frequency**: For widgets like "Value Display," ensure the **Reading Frequency** is set to **PUSH** in the widget settings. Facebook +2

4. Debugging via Serial Monitor

Look for these specific messages in your serial monitor:

- **`Ready (ping: XXms)`**: This means you are online. If you don't see this, use the Blynk Troubleshooting Guide to check your network.
- **`Cmd skipped: 29`**: This often occurs with GSM modules when the data packet is blocked or the server is unreachable. Blynk Community +2

Would you like me to rewrite the specific `loop()` section to include a "retry" logic if the cloud connection is dropped?

I need nextion to send numbers for threshold so that we can update the dashboard according that number but unit just ...

To send actual numbers from the Nextion to the Dashboard, you must change the **Nextion Editor code** to include the numeric value of the `x1` or `x3` components, and then update the **ESP32 code** to "catch" and pull those numbers out of the string.

Recommend
Blynk

1. Update the Nextion Editor (The "Send" part)

Go to your `x1` and `x3` (or the buttons that change them) and update the **Touch Release Event** to send the value along with the prefix:

- **For Temperature (x1):**

```c
print "T"        // Send prefix
prints x1.val,0  // Send the actual number (e.g. 355)
printh 0a        // Send newline so ESP32 knows it's the end
```

Use code with caution.

- **For Humidity (x3):**

```c
print "H"
prints x3.val,0
printh 0a
```

Use code with caution.

---

2. Update the ESP32 Code (The "Receive" part)

Replace your `loop()` with this version. It is designed to look for the **T** or **H**, ignore any "junk" or "noise" characters, and extract only the numbers that follow.

```cpp
void loop() {
  Blynk.run();
  timer.run();

  if (nexSerial.available() > 0) {
    String nexData = nexSerial.readStringUntil('\n');
    nexData.trim();

    // DEBUG: See exactly what is arriving
    Serial.print("Raw from Nextion: "); Serial.println(nexData);

    char type = ' ';
    if (nexData.indexOf('T') != -1) type = 'T';
    else if (nexData.indexOf('H') != -1) type = 'H';

    if (type != ' ') {
      String valStr = "";
      // Loop through the string and grab ONLY the numbers
      for (int i = 0; i < nexData.length(); i++) {
        if (isDigit(nexData[i])) {
          valStr += nexData[i];
        }
      }

      if (valStr.length() > 0) {
        float finalVal = valStr.toFloat() / 10.0; // Convert 355 to 35.5

        if (type == 'T') {
```

```
        if (type == 'T') {
          tempThreshold = finalVal;
          Blynk.virtualWrite(V20, tempThreshold); // UPDATE DASHBOARD
          Serial.print("Temp Threshold Updated to: "); Serial.println(temp
        }
        else if (type == 'H') {
          humThreshold = finalVal;
          Blynk.virtualWrite(V21, humThreshold); // UPDATE DASHBOARD
          Serial.print("Hum Threshold Updated to: "); Serial.println(humTh
        }
      }
    }
  }
}
```

Use code with caution.

Why this works:

1. `prints x1.val,0` : This tells Nextion to send the number as text (like "355") instead of a raw data byte.

2. `isDigit()` : This is a "filter." Even if the A7670C creates electrical noise that adds garbage characters (like `ï¿½`), the code will ignore them and only pick out the `3`, `5`, and `5`.

3. `Blynk.virtualWrite` : By putting this inside the loop, the moment you let go of the button on the screen, the slider on your phone will jump to that exact number.

Once you update the Nextion Editor with the `prints` command, what does the Serial Monitor show when you click the threshold buttons?

Pro-tip: Make sure the **V20** and **V21** datastreams on your Blynk dashboard are set to **"Double"** or **"Integer"** so they can accept the numbers!

Raw from Nextion: □►►►TUP
Raw from Nextion: ...

The characters `ï¿½ï¿½ï¿½` you see are the **Nextion Return Codes** (hexadecimal data like `0x65`) being interpreted as text by your ESP32. The `TUP` is exactly what the display is sending because you programmed that specific string in the Nextion Editor. YouTube +1

To send the actual **numeric value** (like `355` for `35.5`) instead of just the text "TUP", you must use the `prints` command in the Nextion Editor. Athanasios Seitanis +1

1. Update the Nextion Editor

For your **x1** (Temperature) or **x3** (Humidity) buttons, change the **Touch Release Event** to this:

For Temperature Buttons:

```c
print "T"        // Send the identifier
prints x1.val,0  // Send the actual number as text
```

```
printh 0a        // Send the newline character (\n)
```

Use code with caution.

For Humidity Buttons:

```c
print "H"        // Send the identifier
prints x3.val,0  // Send the actual number as text
printh 0a        // Send the newline character (\n)
```

Use code with caution.

2. Complete ESP32 Master Code

This version includes the **Garbage Handler** to ignore the `ï¿½ï¿½ï¿½` and a **Relay Status Reporter** that prints every 5 seconds as requested. YouTube +1

      }
    }
  }
}
```

Use code with caution.

Critical Sync Verification

1. **Check Serial Monitor**: When you press the Nextion button, you should see `SYNC SUCCESS: T Threshold set to 35.5`.
2. **Dashboard Check**: The slider on your phone should move automatically.
3. **Normally Closed Wiring**: Since you mentioned "no current = device works," `LOW` in the code is correct for keeping the machine ON. YouTube

Do you have the 4.7kΩ resistor installed on the DS18B20 sensor data pin?

I did this and now it dosent show any received commands from display on the serial monitor too

If the serial monitor is now completely blank, the ESP32 is not seeing the "end-of-message" character (`\n`) it needs to finish reading the command. This happens because the `prints` command in Nextion is very strict. Arduino Forum +2

1. Fix the Nextion Editor Events

The `prints` command must be followed by a raw **Hexadecimal** newline. Update the **Touch Release Event** for your components `x1` and `x3` to this exact sequence: Nextion

- **For x1 (Temperature Threshold):**

Serial Monito
Arduino

```c
print "T"        // Identifier
prints x1.val,0  // Sends the number as text (e.g., "355")
printh 0a        // CRITICAL: Sends the Line Feed (\n) character
```

Use code with caution.

- **For x3 (Humidity Threshold):**

```c
print "H"
prints x3.val,0
printh 0a        // CRITICAL: Sends the Line Feed (\n) character
```

Use code with caution.

2. Verify Wiring and Power

If it is still blank, the ESP32 might be "hanging" while waiting for data that never arrives. YouTube +1

- **Check the Ground:** Ensure the Nextion **GND** and ESP32 **GND** are physically connected. Without this, the data will be lost.
- **Check TX/RX:** Ensure Nextion **TX** goes to ESP32 **GPIO 32**.
- **Power:** Do not power the Nextion from the ESP32 board; use an external **5V 2A** supply. GitHub +1

3. Use this Robust "Nextion Listener" Code

This version includes a **timeout** so that if the display sends a message without a proper end-character, the ESP32 won't get stuck forever. YouTube

```cpp
void loop() {
  Blynk.run();
  timer.run();

  // Check if Nextion is sending anything
  if (nexSerial.available() > 0) {
    // Read the string but don't wait more than 100ms
    nexSerial.setTimeout(100);
    String nexData = nexSerial.readStringUntil('\n');

    if (nexData.length() > 0) {
      Serial.print("Received from Nextion: ");
      Serial.println(nexData);

      // Process Temperature (T)
      if (nexData.indexOf('T') != -1) {
        String val = extractDigits(nexData, 'T');
        if (val.length() > 0) {
          tempThreshold = val.toFloat() / 10.0;
          Blynk.virtualWrite(V20, tempThreshold);
          Serial.printf("Temp Threshold Sync: %.1f\n", tempThreshold);
```

```
        }
      }
      // Process Humidity (H)
      else if (nexData.indexOf('H') != -1) {
        String val = extractDigits(nexData, 'H');
        if (val.length() > 0) {
          humThreshold = val.toFloat() / 10.0;
          Blynk.virtualWrite(V21, humThreshold);
          Serial.printf("Hum Threshold Sync: %.1f\n", humThreshold);
        }
      }
    }
  }
}

// Helper to filter out garbage and get the numbers
String extractDigits(String data, char marker) {
  String res = "";
  int start = data.indexOf(marker);
  for (int i = start + 1; i < data.length(); i++) {
    if (isDigit(data[i])) res += data[i];
  }
  return res;

}
```

Use code with caution.

Once you re-upload the **.tft** file with the `printh 0a` command, does the "Received from Nextion" text appear in your **Serial Monitor**?

Received from Nextion: □
Received from Nextion: □TUP□

This confirms the wiring is definitely correct, but the Nextion is still sending the **text "TUP"** (from your previous button code) instead of the **number from x1**.

Because your Nextion code says `print "TUP"`, the ESP32 looks for a number after the "T", finds "UP" (which isn't a number), and ignores it.

To fix this, you must change the button code in the **Nextion Editor** to send the **variable value** instead of a fixed word.

1. The Fix in Nextion Editor

Go to the **Touch Release Event** for the button that is currently sending "TUP". Replace that code with this:

C

```
// This sends the actual value of x1 instead of the word "UP"
print "T"
prints x1.val,0
printh 0a
```

Use code with caution.

Do the same for the Humidity button:

```c
print "H"
prints x3.val,0
printh 0a
```

Use code with caution.

2. The Final ESP32 "Garbage-Proof" Code

Use this code. It is designed to ignore the `ï¿½ï¿½ï¿½` junk and look for the number immediately following the "T" or "H".

```cpp
void loop() {
  Blynk.run();
  timer.run();

  if (nexSerial.available() > 0) {
    // Read the incoming string
    String nexData = nexSerial.readStringUntil('\n');
    nexData.trim();

    if (nexData.length() > 0) {
      Serial.print("Raw from Nextion: "); Serial.println(nexData);

      // Check for Temperature Marker
      if (nexData.indexOf('T') != -1) {
        String valStr = "";
        int startPos = nexData.indexOf('T') + 1;

        // Extract only the numbers following 'T'
        for (int i = startPos; i < nexData.length(); i++) {
          if (isDigit(nexData[i])) valStr += nexData[i];
        }

        if (valStr.length() > 0) {
          tempThreshold = valStr.toFloat() / 10.0; // Convert 355 to 35.5
          Blynk.virtualWrite(V20, tempThreshold); // Sync to Blynk Slider
          Serial.printf(">>> SUCCESS: Temp Threshold set to %.1f\n", temp
        }
      }

      // Check for Humidity Marker
      else if (nexData.indexOf('H') != -1) {
        String valStr = "";
        int startPos = nexData.indexOf('H') + 1;

        for (int i = startPos; i < nexData.length(); i++) {
          if (isDigit(nexData[i])) valStr += nexData[i];
        }

        if (valStr.length() > 0) {
          humThreshold = valStr.toFloat() / 10.0;
          Blynk.virtualWrite(V21, humThreshold); // Sync to Blynk Slider
          Serial.printf(">>> SUCCESS: Hum Threshold set to %.1f\n", humTh
        }
      }
```

```
    }
  }
}
```

Use code with caution.

Why it wasn't working:

- **The Problem:** Your Serial Monitor showed `TUP`. The ESP32 saw the `T`, but since `UP` contains no digits, the math failed and the Dashboard didn't update.
- **The Solution:** By using `prints x1.val,0`, the Nextion will send `T355`. The ESP32 will see the `T`, grab the `355`, and update the Dashboard to `35.5`.

Once you re-upload the Nextion file with the `prints x1.val,0` command, what does the Serial Monitor show when you click? (It should now show something like `Raw from Nextion: T355`).

rather then looking for the number just use the TUP and TDN to increase and decrease the reading and HUP and HDN too

To use the **TUP/TDN** and **HUP/HDN** commands for incremental changes, we need to modify the ESP32 logic to look for these specific text strings. Each time it receives a "UP" command, it will add to the threshold; each time it receives a "DN" command, it will subtract.

1. Nextion Editor Setup (Touch Release Event)

Make sure your buttons on the Nextion are sending exactly these strings:

- **Temp Up Button:** `print "TUP"`, then `printh 0a`
- **Temp Down Button:** `print "TDN"`, then `printh 0a`
- **Hum Up Button:** `print "HUP"`, then `printh 0a`
- **Hum Down Button:** `print "HDN"`, then `printh 0a`

---

2. Complete ESP32 Master Code

This code handles the incremental logic, ignores the `ï¿½ï¿½ï¿½` junk, syncs with the Dashboard, and prints the **Relay Status Report** every 5 seconds.

```

```
      Blynk.virtualWrite(V21, humThreshold);
      updateNextionThresholds();
      Serial.println("Nextion: Hum -1.0");
    }
  }
}
```

Use code with caution.

Why this works:

1. `indexOf` **Filter:** By searching for the specific words ("TUP", "TDN", etc.), the code completely ignores the `ï¿½ï¿½ï¿½` junk characters.
2. **Dashboard Sync:** `Blynk.virtualWrite(V20, tempThreshold)` tells your phone to move the slider every time you click the button on the screen.
3. **Nextion Sync:** `updateNextionThresholds()` sends the new calculated value back to the display so the number on the screen changes too.

Does the "Nextion: Temp +0.5" message appear in the Serial Monitor now when you click the buttons?

Check: Ensure you have the **Blynk Auth Token** updated in the code! [1]

change the login in esp code so that when we get data from nextion to dashboard ...

To achieve this, we will update the `loop()` to catch the **TUP/TDN** and **HUP/HDN** strings from the Nextion. When a command is detected, the ESP32 will increment or decrement the local variable and then use `Blynk.virtualWrite` to move the slider on your dashboard.

1. Updated ESP32 Master Code

  sensors.begin();

  nexSerial.begin(9600, SERIAL_8N1, RXD1, TXD1);
  simSerial.begin(115200, SERIAL_8N1, RXD2, TXD2);
  delay(5000);

  Blynk.begin(BLYNK_AUTH_TOKEN, modem, apn, "", "", "blynk.cloud", 80);
  Blynk.syncVirtual(V20, V21, V10);

  timer.setInterval(10000L, sendAllData);
  timer.setInterval(5000L, printRelayStatus);
}

void loop() {
  Blynk.run();
  timer.run();

  if (nexSerial.available() > 0) {
    String nexData = nexSerial.readStringUntil('\n');
    nexData.trim();

    // 1. Process Temperature Commands
    if (nexData.indexOf("TUP") != -1) {
      tempThreshold += 1.0;  // Increase by 1
      Blynk.virtualWrite(V20, tempThreshold); // Update Dashboard
      updateNextionUI(); // Update Screen Number
      Serial.println("Nextion CMD: Temp +1");
    }
    else if (nexData.indexOf("TDN") != -1) {
      tempThreshold -= 1.0;  // Decrease by 1
      Blynk.virtualWrite(V20, tempThreshold);
      updateNextionUI();
      Serial.println("Nextion CMD: Temp -1");
    }

    // 2. Process Humidity Commands
    else if (nexData.indexOf("HUP") != -1) {
      humThreshold += 1.0;   // Increase by 1
      Blynk.virtualWrite(V21, humThreshold);

      updateNextionUI();
      Serial.println("Nextion CMD: Hum +1");
    }
    else if (nexData.indexOf("HDN") != -1) {
      humThreshold -= 1.0;   // Decrease by 1
      Blynk.virtualWrite(V21, humThreshold);
      updateNextionUI();
      Serial.println("Nextion CMD: Hum -1");
    }
```

```
  }
}
```

Use code with caution.

2. Nextion Editor Reminder

For the buttons to trigger this code, their **Touch Release Event** must send the command followed by the newline character:

- **Temp Up:** `print "TUP"`, then `printh 0a`
- **Temp Down:** `print "TDN"`, then `printh 0a`
- **Hum Up:** `print "HUP"`, then `printh 0a`
- **Hum Down:** `print "HDN"`, then `printh 0a`

Why this works:

1. **Dashboard Sync:** `Blynk.virtualWrite(V20, tempThreshold)` forces the slider on your phone to move to the new value immediately after you press the button on the screen.
2. **Display Sync:** `updateNextionUI()` sends the new number to your Nextion's `x1` or `x3` variables, ensuring the number on the screen matches the number on your phone.
3. **No Junk Error:** Since we are searching for the specific words like "TUP," the `ï¿½ï¿½ï¿½` junk is completely ignored.

Does the **Blynk Slider** move on your phone now when you press the **UP** button on the Nextion?

Follow-up: Check if you have set the **V20** and **V21** datastreams in Blynk to **Double** so they accept the incremented values.

there is a water tank button on nextion display that should no be able to controlled manually just by the esp32...

To show images on the Nextion based on the tank status, you need to use the `.pic` attribute of your button (or a Picture object) in the Nextion Editor.

1. Nextion Editor Setup

1. Import two images into your Nextion project:
   - **Image ID 0**: Tank Full image.
   - **Image ID 1**: Tank Empty image.
2. Identify the **Object Name** of your water tank button (e.g., `p0` if it's a picture or `bt1` if it's a button).
3. Make sure the "Touch Press/Release" events for this object are **empty** so the user cannot click it.

2. Updated ESP32 Logic

We will update the `sendAllData` function. It will now send a command to change the image ID (`.pic`) on the Nextion and update the text in Blynk.

cpp

```cpp
void sendAllData() {
  // ... [Existing Temperature/Humidity logic] ...

  // Tank Status Logic (Float Switch)
  int tankStatus = digitalRead(FLOAT_SWITCH);

  if (tankStatus == LOW) { // TANK EMPTY
    // Update Nextion: Change image to ID 1 and text to EMPTY
    nexSerial.print("p0.pic=1"); nexSerial.write(0xff); nexSerial.write(0x
    nexSerial.print("b9.txt=\"EMPTY\""); nexSerial.write(0xff); nexSerial.

    Blynk.virtualWrite(V3, "Empty");
    Serial.println("Status: Tank Empty - Image 1 Set");
  }
  else { // TANK FULL
    // Update Nextion: Change image to ID 0 and text to FULL
    nexSerial.print("p0.pic=0"); nexSerial.write(0xff); nexSerial.write(0x
    nexSerial.print("b9.txt=\"FILLED\""); nexSerial.write(0xff); nexSeria

    Blynk.virtualWrite(V3, "Full");
    Serial.println("Status: Tank Full - Image 0 Set");
  }

  // ... [Existing Blynk virtualWrites for sensors] ...
}
```

Use code with caution.

3. Key Points for Success

- **Object Name**: Replace `p0` in the code with the actual name of your image/button object on the Nextion.
- **Image IDs**: If your images are not ID 0 and 1, change the numbers in `p0.pic=X` to match your Nextion Resource library IDs.
- **Safety**: Since the user shouldn't control this, the `loop()` does **not** contain any listener for this object. The ESP32 is the only master.

Summary of what happens:

1. **Empty Tank**: Float switch drops → ESP32 sees `LOW` → Sends `p0.pic=1` to Nextion → Screen shows **Empty Image**.
2. **Full Tank**: Float switch rises → ESP32 sees `HIGH` → Sends `p0.pic=0` to Nextion → Screen shows **Full Image**.

What are the exact Object Name and Image IDs you are using for the water tank in the Nextion Editor?

give me the entire updated code

This is the **complete, final master code**. It integrates the **A7670C 4G Modem**, **DS18B20**, **SHT45**, **Float Switch**, **7 NC Relays**, and the **Bi-directional Nextion HMI** with the new incremental logic and automated Tank Image switching.

Key Logic Added:

1. **Threshold Step Logic:** Receiving `TUP` / `TDN` or `HUP` / `HDN` from Nextion now changes the threshold by **1.0** and immediately updates the **Blynk Slider**.
2. **Automated Tank Image:** The Nextion object `p0` (Picture/Button) will change to **Pic ID 0 (Full)** or **Pic ID 1 (Empty)** based on the sensor. Manual touch is ignored.
3. **Normally Closed (NC) Safety:** Relays are set to `LOW` to keep the machine running and `HIGH` to stop it.

    }
  }
}
```

Use code with caution.

Nextion Editor Instruction: For the Tank Image to work, ensure the tank picture/button on the screen is named **p0**. If it has a different name, change `p0.pic` in the code to your actual object name.

Do you have the **Picture IDs (0 and 1)** assigned to the correct images in your Nextion resource list?

AI can make mistakes, so double-check responses

the water tank button is named b6

To update the water tank status on your Nextion display using the button named **b6**, we will use the `.pic` (for background image) or `.pic2` (for the pressed state image) attributes.

Below is the **complete, final master code**. I have updated the tank logic to target **b6** and included all the bi-directional threshold syncing, relay status reporting, and 4G connectivity.

Master Wiring Check

- **Modem (A7670C):** TX → 16, RX → 17
- **Nextion HMI:** TX → 32, RX → 33
- **Sensors:** DS18B20 (4), SHT45 (21/22), Float Switch (13)
- **Relays (NC):** 2, 12, 14, 15, 25, 26, 27 (**LOW = ON**)

  }
}
```

Use code with caution.

Nextion Setting Reminder:

- Ensure **Image 0** is your "Full" tank and **Image 1** is your "Empty" tank.
- Make sure button **b6** has its `vtype` set to **crop image** or **image** so it can change pictures.

Does the tank button **b6** change its icon correctly now when you move the float switch?

Follow-up: Check if you need an **alarm buzzer** to sound if the tank stays empty for too long.

the id of full tank is id10 and empty is id13

To update the water tank button **b6** with **Image ID 10 (Full)** and **Image ID 13 (Empty)**, I have updated the `.pic` and `.pic2` (pressed state) commands in the logic below.

1. Nextion Command Logic

- **Tank Full:** `b6.pic=10` and `b6.pic2=10`
- **Tank Empty:** `b6.pic=13` and `b6.pic2=13`

2. Final Master Code (Complete)

    else if (nexData.indexOf("HDN") != -1) { humThreshold -= 1.0; Blynk.v
  }
}
```

Use code with caution.

Final Nextion Checks:

1. Verify **Image ID 10** is your **Full** tank and **Image ID 13** is your **Empty** tank in the Resource Library.
2. Ensure button **b6** is set to `vtype=image` so it can swap pictures.
3. Ensure the **4.7kΩ pull-up resistor** is on the DS18B20 data pin for stable readings.

Does the **b6** button now swap between **ID 10** and **ID 13** correctly?

Follow-up: Should we add a **Blynk notification** to your phone when the tank stays empty for too long?

now for both the heater switch on the display
if the primary heater is off turn the secondary one off too ...

To implement this, we use a **Master-Slave Relay Logic**: Relay 2 (Secondary Heater) is physically and logically dependent on Relay 1 (Primary Heater). If Relay 1 is OFF, Relay 2 is forced OFF regardless of temperature. We also link Nextion buttons `bt1` (Primary) and `bt2` (Secondary) to Blynk `V11` and `V12`.

1. Nextion Editor Setup

- **bt1 (Primary):** Dual-state button. Touch Release: `print "R1"`, `print bt1.val`, `printh 0a`
- **bt2 (Secondary):** Dual-state button. Touch Release: `print "R2"`, `print bt2.val`, `printh 0a`

Use code with caution

Use code with caution.

Nextion Logic: When you turn **Heater 1 OFF** on the screen, the ESP32 will instantly send a command back to the screen to turn **Heater 2 OFF** as well.

Does the **Secondary Heater button** on the Nextion correctly flip to **OFF** when you manually switch the **Primary Heater** to **OFF**?

the on and off must be visible on both side dashboard and nextion where ever we change

To achieve perfect **bi-directional synchronization** for the heaters, the ESP32 must act as the master bridge. When you flip a switch on the **Dashboard**, the ESP32 updates the **Relay** and the **Nextion Display**. When you flip a switch on the **Nextion**, the ESP32 updates the **Relay** and the **Blynk Dashboard**.

1. The Logic Rules (NC Wiring)

- **Safety Rule:** If Primary Heater (`bt1` / `V11`) is **OFF**, the Secondary Heater (`bt2` / `V12`) is automatically forced **OFF**.
- **NC Logic:** `1` (HIGH) = Relay Open (**Device STOPPED**), `0` (LOW) = Relay Closed (**Device WORKING**).

2. Nextion Editor Setup (Buttons)

Ensure your Dual-State buttons on Nextion are programmed as follows:

- **bt1 (Primary):** Touch Release Event: `print "R1"`, `print bt1.val`, `printh 0a`
- **bt2 (Secondary):** Touch Release Event: `print "R2"`, `print bt2.val`, `printh 0a`

    }
    // ... [Add your TUP/TDN logic here from previous steps] ...
  }
}
```

Use code with caution.

How to use:

1. **Dashboard -> Screen:** Toggle **V11** on your phone. Relay 1 clicks, and the Nextion button **bt1** flips its state automatically.
2. **Screen -> Dashboard:** Press **bt1** on the Nextion. Relay 1 clicks, and the **V11 switch** on your phone moves automatically.
3. **The Safety Lock:** If you turn **Primary OFF**, both the Dashboard and the Screen will

show **Secondary OFF** instantly.

Does the **Primary Heater** status now update on your phone immediately when you press the button on the **Nextion Display**?

the primary heater switch name on nextion is sw0 and for secondary its sw1

To sync with the **Nextion Dual-State Switches (`sw0` and `sw1`)**, we update the command strings to target those specific names. In Nextion, `sw` components use the `.val` attribute just like buttons.

1. Nextion Editor Events

Ensure your switches on the Nextion have these commands in their **Touch Release Event**:

- **sw0 (Primary):** `print "R1"`, `print sw0.val`, `printh 0a`
- **sw1 (Secondary):** `print "R2"`, `print sw1.val`, `printh 0a`

    else if (nexData.indexOf("TDN") != -1) { tempThreshold -= 1; Blynk.vi
  }
}
```

Use code with caution.

Key Changes:

1. **Targeted `sw0` and `sw1`**: The `syncHeaterUI` function now correctly commands the Nextion switches.
2. **Master Slave Safety**: The code ensures Relay 1 must be active (LOW) for Relay 2 to work, and this is visually reflected on both the dashboard and the screen instantly.

Do the **Nextion switches `sw0` and `sw1`** now flip their positions when you toggle them from the **Blynk phone app**?

thers a little issue when I switched on the dashboard it gets off on the display and vice versa for both heater switch

This happens because the **Nextion Switch (`sw`)** component and the **Blynk Switch** are interpreted with opposite logic (Inversion). In Nextion, `val=0` usually looks "Off" and

`val=1` looks "On." In our code, we were sending the **Relay State**, where `0` means **Working (On)** and `1` means **Stopped (Off)**.

To fix this, we simply **invert the value** before sending it to the display and the dashboard.

1. The Logic Fix

- **Physical Relay:** `0` = ON, `1` = OFF.
- **Nextion/Blynk UI:** `1` = ON (Visual), `0` = OFF (Visual).

2. Final Master Code (Integrated)

    else if (nexData.indexOf("TDN") != -1) { tempThreshold -= 1; Blynk.vi
  }
}
```

Use code with caution.

Nextion Setting Reminder:

In your **Nextion Editor**, for switches **sw0** and **sw1**, ensure the **Touch Release Event** code sends the numeric value as before:

- `print "R1"`, `print sw0.val`, `printh 0a`
- `print "R2"`, `print sw1.val`, `printh 0a`

Does the On/Off state on the phone now match the On/Off state on the display?

also the fact that the secondary heater must be controlled by the esp too according to the threshold of the temprature

To finalize the logic, we will integrate the **Heater Threshold Control** directly into the `sendAllData` loop.

The Automated Logic

1. **Primary Heater:** Stays on as long as `avgTemp` < `tempThreshold`.

2. **Secondary Heater:** Only activates if the **Primary is already ON** AND the temperature is significantly lower than the threshold (e.g., `tempThreshold - 5.0`).
3. **Manual Override:** If you manually flip a switch on the App or Screen, the Auto-logic for that specific heater pauses until the next data cycle.

```

```
    else if (nexData.indexOf("IDN") != -1) { tempThreshold -= 1; Blynk.vi
  }
}
```

Use code with caution.

Nextion Setting Reminder:

- **sw0** and **sw1** will now move to the "ON" or "OFF" position automatically based on the sensor logic.
- The **Primary Heater** must be in the "ON" state for the **Secondary Heater** to even be considered by the Auto-logic.

Does the Secondary Heater now kick in automatically when the temperature drops 5 degrees below your set threshold?

the primary heater always stay on it can only be turned of manually not by logic

To implement this, we remove the `tempThreshold` check from the **Primary Heater (R_HEAT1)** logic. It will now only respond to manual commands from the **Blynk App** or the **Nextion Display**. The **Secondary Heater (R_HEAT2)** remains automated but follows your safety rule: it only turns on if the Primary is already running.

    else if (nexData.indexOf("TDN") != -1) { tempThreshold -= 1; Blynk.vir
  }
}
```

Use code with caution.

Summary of what changed:

1. **Primary Heater Independence:** The `digitalWrite(R_HEAT1, ...)` command has been removed from the automatic `sendAllData` loop. It will now stay in whatever state you set it to (On or Off) via the Dashboard or Screen.
2. **Safety Override:** Even though the Primary is manual, the **Secondary** will still force-shut if the temperature exceeds your threshold, protecting the machine from overheating.

Does the Primary Heater now stay at your manual setting regardless of the temperature?

a little issue with the switches is left as I told earlier when I turn on the dashboard it shows off on the display

This issue occurs because of a mismatch between the **ESP32 Relay Logic** (where 0 is ON) and the **UI Logic** (where 1 is ON).

In the previous code, the `syncHeaterUI` function was sending the raw relay state to the Nextion. We need to **invert** that value so that when the Relay is **0 (ON)**, the Nextion Switch gets a **1 (ON)**.

The Fix

I have updated the `syncHeaterUI` and `BLYNK_WRITE` functions to ensure the icons and sliders move together correctly.

  delay(5000);
  Blynk.begin(BLYNK_AUTH_TOKEN, modem, apn, "", "", "blynk.cloud", 80);
  timer.setInterval(10000L, sendAllData);
}

void loop() {
  Blynk.run();
  timer.run();
  if (nexSerial.available() > 0) {
    String nexData = nexSerial.readStringUntil('\n'); nexData.trim();

    if (nexData.startsWith("R1")) {
      int s = nexData.substring(2).toInt(); // Nextion sends 1 for ON
      digitalWrite(R_HEAT1, (s == 1) ? 0 : 1);
      if (s == 0) digitalWrite(R_HEAT2, 1);
      syncHeaterUI();
    }
    else if (nexData.startsWith("R2")) {
      int s = nexData.substring(2).toInt();
      if (digitalRead(R_HEAT1) == 0) digitalWrite(R_HEAT2, (s == 1) ? 0 :
      else digitalWrite(R_HEAT2, 1);
      syncHeaterUI();
    }
    else if (nexData.indexOf("TUP") != -1) { tempThreshold += 1; Blynk.vi
    else if (nexData.indexOf("TDN") != -1) { tempThreshold -= 1; Blynk.vi
  }
}
```

Use code with caution.

Nextion Instruction: Ensure your `sw0` and `sw1` components in the Editor have `print "R1"`, `print sw0.val`, `printh 0a` in their events.

Does the **ON/OFF state** on the phone now match the **ON/OFF position** of the switch on the display?

Follow-up: Check if you need a **physical emergency stop button** as a fail-safe for the heaters.

noe still goes opposite

If the switches are still opposite (turning ON on the phone makes it look OFF on the screen), it means your **Nextion Switch component** or your **Blynk Widget** is set to

"Inverted" mode.

To fix this once and for all, we will swap the `1` and `0` logic specifically for the Nextion commands.

The Logic Correction

1. **ESP32 Relay:** `0` = Physical ON, `1` = Physical OFF.
2. **Blynk App:** `1` = Visual ON, `0` = Visual OFF.

3. **Nextion Switch:** We will now send `0` to look **ON** and `1` to look **OFF** (to match your specific HMI design).

Updated Sync Function

Replace your `syncHeaterUI` and `BLYNK_WRITE` functions with this version:

cpp

```cpp
void syncHeaterUI() {
  int r1 = digitalRead(R_HEAT1);
  int r2 = digitalRead(R_HEAT2);

  // 1. Update Blynk (1 = ON, 0 = OFF)
  int blynk1 = (r1 == 0) ? 1 : 0;
  int blynk2 = (r2 == 0) ? 1 : 0;
  Blynk.virtualWrite(V11, blynk1);
  Blynk.virtualWrite(V12, blynk2);

  // 2. Update Nextion (SWAPPING LOGIC: 0 = Visual ON, 1 = Visual OFF)
  int nex1 = (r1 == 0) ? 0 : 1;
  int nex2 = (r2 == 0) ? 0 : 1;
  nexSerial.print("sw0.val=" + String(nex1)); nexSerial.write(0xff); nexS
  nexSerial.print("sw1.val=" + String(nex2)); nexSerial.write(0xff); nexS
}

// Update the Nextion Listener in loop() as well
if (nexData.startsWith("R1")) {
    int s = nexData.substring(2).toInt();
    // If Nextion sends 0, we turn Relay ON (0)

    digitalWrite(R_HEAT1, (s == 0) ? 0 : 1);
    if (s == 1) digitalWrite(R_HEAT2, 1);
    syncHeaterUI();
}
```

Use code with caution.

Why this happens

Nextion switches have two attributes: `val` and `pic` (or background color). If your Nextion project was designed so that the "On" image is shown when `val` is `0`, the code must send a `0` to represent "On."

Quick Physical Test

1. Turn the switch **ON** on your phone.
2. Check the **Relay** (it should click and turn the heater on).
3. Check the **Nextion**.
   - If it still looks **OFF**, change the `nex1` line in the code above to: `int nex1 = (r1 == 0) ? 1 : 0;` (Revert to standard)
   - If it looks **ON**, you are done!

Does the switch on the Nextion screen move to the correct "ON" position now when you toggle it from your phone?

Follow-up: Are you using **Custom Images** for the switch states in the Nextion Editor, or the **default green/grey** colors?

give the whole code

To fix the inversion once and for all, this version of the code separates the **Physical Relay Logic** from the **UI Display Logic**.

Logic used here:

1. **Relays:** `0` (LOW) = Working/ON, `1` (HIGH) = Stopped/OFF.
2. **Blynk/Nextion UI:** `1` = Visual ON, `0` = Visual OFF.
   If your Nextion switches still appear opposite, you can simply swap the `1` and `0` in the `updateNextionUI` function below.

      syncHeaterUI();
    }
    else if (nexData.startsWith("R2")) {
      int s = nexData.substring(2).toInt();
      if (digitalRead(R_HEAT1) == 0) digitalWrite(R_HEAT2, (s == 1) ? 0 :
      else digitalWrite(R_HEAT2, 1);
      syncHeaterUI();
    }
    else if (nexData.indexOf("TUP") != -1) { tempThreshold += 1; Blynk.vir
    else if (nexData.indexOf("TDN") != -1) { tempThreshold -= 1; Blynk.vir
  }
}
```

Use code with caution.

Nextion "Touch Release" Event Reminder:

- **sw0 (Primary):** `print "R1"`, `print sw0.val`, `printh 0a`
- **sw1 (Secondary):** `print "R2"`, `print sw1.val`, `printh 0a`
- **TUP/TDN:** `print "TUP"`, `printh 0a` (and similar for others).

Does the **visual position** of the switches on the screen and phone match **exactly** now?

Follow-up: Check if you need an **automatic data logging feature** to save the temperature history to a CSV file or Google Sheets.

I cant switch or or off from the display why so?

If the display isn't switching the relays, the **ESP32 is not receiving the "R1" or "R2" command strings** from the Nextion. This is almost always due to the **Component ID** interference or the specific **Nextion command syntax**.

1. The Fix in Nextion Editor (Must Do)

Nextion switches (`sw0` , `sw1`) do not send data to the Serial port by themselves. You must manually add the code to their **Touch Release Event**.

1. Open the **Nextion Editor**.
2. Click on **sw0** (Primary Heater).
3. In the **Event** window (bottom right), go to the **Touch Release Event** tab.
4. **UNCHECK** "Send Component ID" (if checked).
5. Type this exactly (one command per line):

```c
print "R1"
prints sw0.val,0
printh 0a
```

Use code with caution.

6. Repeat for **sw1** (Secondary Heater):

```c
print "R2"
prints sw1.val,0
printh 0a
```

Use code with caution.

7. **Compile** and re-upload the `.tft` file to the display.

2. Why it's not switching right now

- **The Identifier:** The ESP32 is looking for a string starting with **"R1"**. If you are only sending the number or a different word, the `if (nexData.startsWith("R1"))` check in the code will fail.
- **The Newline:** The `printh 0a` is the "Enter" key for the ESP32. Without it, the ESP32 waits forever for the end of the sentence and never acts.
- **The Prints Command:** Using `prints sw0.val,0` ensures the value is sent as a text character ('0' or '1') instead of a raw data byte that looks like garbage (`ï¿½`).

3. Verify in Serial Monitor

Open the Arduino Serial Monitor and flip the switch on the Nextion.

- **If you see nothing:** Check your wiring (Nextion TX to ESP32 Pin 32).
- **If you see "Raw from Nextion: R11":** The code will work perfectly.
- **If you see "Raw from Nextion: ï¿½":** You still have the "Send Component ID" box checked.

After re-uploading the Nextion file with the `prints` and `printh 0a` commands, does the "Raw from Nextion" text show up?

lets get on the work light switch on dashboard and button on the display...

To make the **Work Light** perfectly interconnected, we will use **Relay 0 (GPIO 2)** and link it to **Blynk V10** and Nextion Dual-state button **bt0**.

Just like the heaters, we use **Inversion Logic** so that **Visual ON (1)** on your screens equals **Physical ON (0/LOW)** on your NC relay.

1. Nextion Editor Setup (Work Light)

Select your dual-state button **bt0** and go to the **Touch Release Event**:

1. **Uncheck** "Send Component ID".
2. Type this exact code:

c

```
print "L"
prints bt0.val,0
printh 0a
```

Use code with caution.

2. Updated Master Code (Full Integration)

  timer.run();
  if (nexSerial.available() > 0) {
    String nexData = nexSerial.readStringUntil('\n'); nexData.trim();

    // Work Light Sync (L)
    if (nexData.startsWith("L")) {
      int s = nexData.substring(1).toInt();
      digitalWrite(R_LIGHT, (s == 1) ? 0 : 1);
      syncAllInterfaces();
    }
    // Heaters Sync (R1/R2)
    else if (nexData.startsWith("R1")) {
      int s = nexData.substring(2).toInt(); digitalWrite(R_HEAT1, (s == 1
      if (s == 0) digitalWrite(R_HEAT2, 1); syncAllInterfaces();
    }
    else if (nexData.startsWith("R2")) {
      int s = nexData.substring(2).toInt(); if (digitalRead(R_HEAT1) == 0
      else digitalWrite(R_HEAT2, 1); syncAllInterfaces();
    }
    // Threshold Sync
    else if (nexData.indexOf("TUP") != -1) { tempThreshold += 1; Blynk.vi
    else if (nexData.indexOf("TDN") != -1) { tempThreshold -= 1; Blynk.vi
  }
}
```

Use code with caution.

Why this works:

1. **Shared Sync Function:** `syncAllInterfaces()` now updates the Work Light (**bt0**), Primary Heater (**sw0**), and Secondary Heater (**sw1**) on Nextion and Blynk at the same time.
2. **Clean Command:** Nextion sends "L1" for ON or "L0" for OFF. The ESP32 parses the "L", updates the Relay, and then tells the Blynk Dashboard to flip its switch to match.
3. **Boot Sync:** `Blynk.syncVirtual` in `setup()` pulls the last known state from the cloud so your screen doesn't "reset" to OFF when you power up.

Does the Work Light now flip on both your phone and the screen when you touch either one?

Follow-up: Check if you need to add a **timer function** for the Work Light so it turns off automatically after a certain period.

the light stays on on the display and also its not interlinked with the dashboard

The reason your **Work Light** is not interlinked is because the **Nextion Dual-State Button (bt0)** requires a specific refresh command to change its visual state, and the **ESP32** needs to explicitly broadcast that change to the **Blynk Dashboard**.

Here is the fixed logic and the final integrated code.

1. Fix the Nextion Editor (Display to Phone)

Your **bt0** button must tell the ESP32 when it is touched.

1. Open **Nextion Editor** and click on **bt0**.
2. In the **Touch Release Event**:
   - **Uncheck** "Send Component ID".
   - Type:

```c
print "L"
print bt0.val
printh 0a
```

Use code with caution.

2. Final Master Integrated Code (Phone ↔ Screen ↔ Relay)

    else if (nexData.indexOf("TDN") != -1) { tempThreshold -= 1; Blynk.vi
  }
}
```

Use code with caution

Why this works:

1. **Bi-directional Sync**: Toggling the button on your phone triggers `BLYNK_WRITE`, which calls `syncAllInterfaces()`, sending `bt0.val=...` to the Nextion. The screen button flips immediately.
2. **Screen to Phone**: Pressing the Nextion button sends `L1` or `L0`. The `loop()` catches this, updates the relay, and calls `Blynk.virtualWrite(V10, ...)`, moving the switch on your phone.
3. **Normally Closed Wiring**: The code handles the logic inversion (`1` on UI = `0` on Relay) so "ON" always means the machine is working.

After uploading the code and updating the Nextion bt0 event, does the phone app switch move when you press the button on the screen?

check what it is sending and fix the issue as when I click from dashboard it changes pn the display but not the other way ...

The issue is that the **Nextion Display** needs to be told exactly what to send to the ESP32. By default, it sends hidden "Hex" codes that the ESP32 can't read as text. To fix the bi-directional sync for the **Work Light** and other switches, you must update the **Nextion Editor** events and use the refined **ESP32 code** below.

1. Fix the Nextion Editor (Crucial)

For the display to update the dashboard, every button must "shout" its new value to the ESP32. Set these in the **Touch Release Event** tab for each component:

- **bt0 (Work Light):**

```c
print "L"       // Prefix
print bt0.val   // Sends 0 or 1
printh 0a       // Sends the "Enter" key (\n)
```

Use code with caution.

- **sw0 (Primary Heater):**

```c
print "R1"
print sw0.val
printh 0a
```

Use code with caution.

- **sw1 (Secondary Heater):**

```c
print "R2"
print sw1.val
printh 0a
```

Use code with caution.

Note: Make sure the **"Send Component ID"** checkbox is **UNCHECKED** for all these buttons.

2. Complete Integrated Master Code

This code handles the **Inversion Logic** (NC Relays), **Threshold Sync**, and **Bi-directional Updates**.

```cpp

    else if (nexData.indexOf("TDN") != -1) { tempThreshold -= 1; Blynk.vi
  }
}
```

Use code with caution.

Check the Serial Monitor: When you press the **bt0** button on the Nextion, does the Serial Monitor show **"Nextion Command: L1"**? If it does, the dashboard switch will flip instantly.

Does the **Work Light** now sync between your phone and the screen when you update the Nextion Editor with the `print` commands?

the serial monitor shows nothing

If the **Serial Monitor shows nothing** when you touch the Nextion screen, **the ESP32 is not receiving any electrical signals from the display**. Since Dashboard → Screen works, your ESP32's **TX** (sending) path is fine, but the **RX** (receiving) path is broken.

1. The Physical Wiring Test (Most Likely)

Check these three things immediately:

- **Nextion TX to ESP32 RX (GPIO 32)**: Ensure the wire from the Nextion **TX** pin is connected to ESP32 **GPIO 32**. If they are not crossed (TX to RX), data cannot flow to the ESP32. [1, 2]
- **Common Ground**: Ensure there is a **physical wire** connecting a **GND pin** on the Nextion directly to a **GND pin** on the ESP32. Without a shared ground, the serial signal has no reference and will be ignored. [3]
- **Voltage Levels**: ESP32 pins are **3.3V**. Some Nextion displays output **5V**. If you don't have a logic level shifter, the ESP32 might be struggling to read the signal or the pin may be protecting itself. [2]

2. Nextion Editor "Release Event" Check

Even with perfect wiring, the screen remains silent unless the button is programmed to speak.

1. Open **Nextion Editor** → Click **bt0**.
2. Look at the **Touch Release Event** tab.
3. Ensure **"Send Component ID"** is **UNCHECKED**.
4. Use this exact code (one command per line):

Something went wrong and the content wasn't generated.

the id of image when its on is 12 and when off is 11

To fix the bi-directional sync for the **Work Light** (Relay 0 / Pin 2) and ensure the images (**ID 12 for ON**, **ID 11 for OFF**) update correctly on the Nextion button **bt0**, use the code below.

1. Nextion Editor Setup (Critical)

For the display to talk to the Dashboard, **bt0** must send its state.

1. Click **bt0** -> **Touch Release Event**.
2. **Uncheck** "Send Component ID".
3. Enter this exact code:

c

```
print "L"
print bt0.val
printh 0a
```

Use code with caution.

2. Final Master Integrated Code

cpp

  Blynk.begin(BLYNK_AUTH_TOKEN, modem, apn, "", "", "blynk.cloud", 80);
  Blynk.syncAll();
  timer.setInterval(10000L, sendAllData);
}

void loop() {
  Blynk.run();
  timer.run();

  if (nexSerial.available() > 0) {
    String nexData = nexSerial.readStringUntil('\n'); nexData.trim();

    if (nexData.startsWith("L")) { // Work Light Sync
      int s = nexData.substring(1).toInt();
      digitalWrite(R_LIGHT, (s == 1) ? 0 : 1);
      syncAllInterfaces();
    }
    else if (nexData.startsWith("R1")) {

      int s = nexData.substring(2).toInt();
```

```
      digitalWrite(R_HEAT1, (s == 1) ? 0 : 1);
      if (s == 0) digitalWrite(R_HEAT2, 1);
      syncAllInterfaces();
    }
    else if (nexData.startsWith("R2")) {
      int s = nexData.substring(2).toInt();
      if (digitalRead(R_HEAT1) == 0) digitalWrite(R_HEAT2, (s == 1) ? 0 :
      else digitalWrite(R_HEAT2, 1);
      syncAllInterfaces();
    }
  }
}
```

Use code with caution.

Why Serial Monitor might be silent:

If you still see nothing in Serial Monitor when you touch the screen, please **swap your wires on GPIO 32 and 33** once to ensure TX/RX aren't reversed, and verify that the **GND** wire is shared between the ESP32 and Nextion.

Does the Work Light image (ID 12) now appear on the screen when you turn it ON from your phone?

I hsould be able to click on the screen too to control and also from the dashboard rn it is working partially

To make the **Work Light** (Relay 0 / Pin 2) fully controllable from **both sides** (Nextion Screen and Blynk Dashboard), we must ensure the ESP32 is actively listening for the "L" command.

If it works from the Dashboard but not the Screen, the **Nextion is not sending the message** or the **ESP32 is not reading the specific termination character**.

1. The "Nextion Side" Fix (Must do first)

Go to the **Nextion Editor** and click on your **bt0** button. In the **Touch Release Event**, you must use this exact code to ensure the ESP32 "hears" the change:

```c
// This tells the ESP32: "L" is for Light, and "bt0.val" is 0 or 1
print "L"
print bt0.val
printh 0a // This is the "Enter" key (\n) that the ESP32 waits for
```

Use code with caution.

- **Checkbox:** Ensure **"Send Component ID"** is **UNCHECKED**.

---

2. The "ESP32 Side" Fix (Full Code)

This code includes a **Debug Monitor**. If you press the button on the screen, it will print

exactly what it received to your PC Serial Monitor.

  syncAllInterfaces();
}

void setup() {
```

```
  Serial.begin(115200);
  for (int i=0; i<7; i++) { pinMode(relayPins[i], OUTPUT); digitalWrite(re
  pinMode(FLOAT_SWITCH, INPUT_PULLUP);

  Wire.begin();
  if (sht4.begin()) shtFound = true;
  sensors.begin();

  nexSerial.begin(9600, SERIAL_8N1, RXD1, TXD1);
  simSerial.begin(115200, SERIAL_8N1, RXD2, TXD2);
  delay(5000);

  Blynk.begin(BLYNK_AUTH_TOKEN, modem, apn, "", "", "blynk.cloud", 80);
  Blynk.syncVirtual(V10); // Sync Work Light on boot

  timer.setInterval(10000L, [](){ syncAllInterfaces(); }); // Keep UI sync
}

void loop() {
  Blynk.run();
  timer.run();

  // Screen -> ESP -> Phone
  if (nexSerial.available() > 0) {
    String nexData = nexSerial.readStringUntil('\n');
    nexData.trim();

    if (nexData.length() > 0) {
      Serial.print("DEBUG: Nextion sent -> ");
      Serial.println(nexData);

      if (nexData.startsWith("L")) {
        int s = nexData.substring(1).toInt(); // Get 0 or 1
        digitalWrite(R_LIGHT, (s == 1) ? 0 : 1);
        syncAllInterfaces();
      }
    }
  }
}
```

Use code with caution.

Why it was "Working Partially":

- **Dashboard → Screen:** Works because the ESP32 is sending a command (`bt0.val=1`) that Nextion understands natively.
- **Screen → Dashboard:** Fails if the Nextion doesn't send the `\n` (`printh 0a`). The ESP32 waits forever for the end of the message and never updates the Dashboard.

After uploading this, click the button on the screen. Does the Serial Monitor show **"DEBUG: Nextion sent -> L1"**?

Follow-up: Check your **Nextion TX to ESP32 Pin 32** wire. If the Serial Monitor is still silent when you touch the screen, that wire is likely loose.

why did the TUP TDN logic stop working

The logic likely stopped working because we replaced the general **Nextion Listener** with a specific one for the **Work Light ("L")** in the last snippet, accidentally removing the `if` statements for **TUP** and **TDN**.

To fix this, we need to combine all "listeners" into one `loop()` so the ESP32 can check for **T** (Temperature), **H** (Humidity), **L** (Light), and **R** (Heater Relays) all at once.

Updated Integrated Loop

Replace your current `loop()` with this version to restore all functions:

cpp

```cpp
void loop() {
  Blynk.run();
  timer.run();

  if (nexSerial.available() > 0) {
    String nexData = nexSerial.readStringUntil('\n');
    nexData.trim();

    if (nexData.length() > 0) {
      Serial.print("Nextion Data Received: ");
      Serial.println(nexData);

      // 1. Work Light Logic (L)
      if (nexData.startsWith("L")) {
        int s = nexData.substring(1).toInt();
        digitalWrite(R_LIGHT, (s == 1) ? 0 : 1);
        syncAllInterfaces();
      }
      // 2. Temp Threshold Logic (TUP/TDN)
      else if (nexData.indexOf("TUP") != -1) {
        tempThreshold += 1.0;
        Blynk.virtualWrite(V20, tempThreshold);
        syncAllInterfaces();
        Serial.println("Action: Temp Threshold +1");
      }
      else if (nexData.indexOf("TDN") != -1) {
        tempThreshold -= 1.0;
        Blynk.virtualWrite(V20, tempThreshold);
        syncAllInterfaces();
        Serial.println("Action: Temp Threshold -1");
      }
      // 3. Humidity Threshold Logic (HUP/HDN)
      else if (nexData.indexOf("HUP") != -1) {
        humThreshold += 1.0;
        Blynk.virtualWrite(V21, humThreshold);
        syncAllInterfaces();
        Serial.println("Action: Hum Threshold +1");
      }
      else if (nexData.indexOf("HDN") != -1) {
        humThreshold -= 1.0;
        Blynk.virtualWrite(V21, humThreshold);
        syncAllInterfaces();
        Serial.println("Action: Hum Threshold -1");
      }
      // 4. Heater Relays (R1/R2)
      else if (nexData.startsWith("R1")) {
        int s = nexData.substring(2).toInt();
        digitalWrite(R_HEAT1, (s == 1) ? 0 : 1);
        if (s == 0) digitalWrite(R_HEAT2, 1);
        syncAllInterfaces();
      }
      else if (nexData.startsWith("R2")) {
        int s = nexData.substring(2).toInt();
```

```
        if (digitalRead(R_HEAT1) == 0) digitalWrite(R_HEAT2, (s == 1) ? 0
        else digitalWrite(R_HEAT2, 1);
        syncAllInterfaces();
      }
    }
  }
}
```

Use code with caution.

Why it stopped:

The ESP32 processes serial data line-by-line. If the code only looks for `startsWith("L")`, it completely ignores anything containing `TUP`. By using `else if` chains, the ESP32 checks every possibility for every message received.

Nextion Reminder:

For the buttons to work, ensure your Nextion Editor "Touch Release" events still have the `printh 0a` at the end:

- `print "TUP"`, then `printh 0a`
- `print "TDN"`, then `printh 0a`

Does the Serial Monitor now show "Action: Temp Threshold +1" when you press the Nextion button?

also when it gets a L for light make the light and and when we get the L again make it off and change the images on the ...

To make the **Work Light** (Relay 0 / Pin 2) toggle correctly and sync with the **Blynk Dashboard** and **Nextion Images (ON=12, OFF=11)**, we need to update the `loop()` logic to handle the "L" command as a toggle.

1. Nextion Editor Setup (Button bt0)

Ensure your **Work Light button (bt0)** in the Nextion Editor has this code in its **Touch Release Event**:

```c
print "L"
printh 0a
```

Use code with caution.

(This sends just the letter "L" and a newline, letting the ESP32 handle the state switching).

2. Full Integrated Master Code

```cpp
```

```
 . .

  delay(5000);
  Blynk.begin(BLYNK_AUTH_TOKEN, modem, apn, "", "", "blynk.cloud", 80);
  Blynk.syncAll();
  timer.setInterval(10000L, sendAllData);
}

void loop() {
  Blynk.run();
  timer.run();

  if (nexSerial.available() > 0) {
    String nexData = nexSerial.readStringUntil('\n'); nexData.trim();

    // --- TOGGLE LIGHT (L) ---
    if (nexData == "L") {
      int currentState = digitalRead(R_LIGHT);
```

```
      digitalWrite(R_LIGHT, !currentState); // Flip the current state
      syncAllInterfaces(); // Update Blynk and Nextion Images
      Serial.print("Light Toggled to: "); Serial.println(digitalRead(R_LI(
    }
    // --- THRESHOLDS ---
    else if (nexData.indexOf("TUP") != -1) { tempThreshold += 1; syncAllI
    else if (nexData.indexOf("TDN") != -1) { tempThreshold -= 1; syncAllI
    else if (nexData.indexOf("HUP") != -1) { humThreshold += 1; syncAllIn
    else if (nexData.indexOf("HDN") != -1) { humThreshold -= 1; syncAllIn
    // --- HEATERS ---
    else if (nexData.startsWith("R1")) {
      int s = nexData.substring(2).toInt(); digitalWrite(R_HEAT1, (s == 1
      if (s == 0) digitalWrite(R_HEAT2, 1); syncAllInterfaces();
    }
    else if (nexData.startsWith("R2")) {
      int s = nexData.substring(2).toInt(); if (digitalRead(R_HEAT1) == 0
      else digitalWrite(R_HEAT2, 1); syncAllInterfaces();
    }
  }
}
```

Use code with caution.

Why this works:

1. **Toggle Logic:** In the `loop()`, when it receives "L", it reads the current pin state with `digitalRead` and flips it using `!`.
2. **Image Sync:** The `syncAllInterfaces()` function explicitly sends `bt0.pic=12` (ON) or `bt0.pic=11` (OFF) every time the light state changes.
3. **Real-Time Sync:** Because `syncAllInterfaces()` is called immediately after the toggle, your **Blynk Dashboard** switch will also flip to match the screen.
